## **Declaration**

I, Sagar Kumar (2013RME9049) declare that this thesis titled “**Design, Development and Analysis of Rapid tooling mold and mold inserts for minimum Shrinkage and Warp**age” and the work presented in it , are my own. I confirm that:

- This work was done wholly or mainly while in candidature for a research degree at this University.
- Where ant part of this thesis has previously been submitted for a degree or any other qualification at this university or any other institution, this has been clearly stated.
- Where I have consulted the published work of others this is always clearly attributed.
- Where I have quoted from the work of others, the source is always given. With the expectation of such quotations, this thesis is entirely my own work.
- I have acknowledged all main sources of help.
- Where the thesis is based on work done by myself, jointly with others, I have made clearly exactly what was done by others and what I have contributed myself.

Date:

**Sagar Kumar**  
(2013RME9049)

## **Certificate**

This is to certify that the thesis entitled “**Design, Development and Analysis of Rapid tooling mold and mold inserts for minimum Shrinkage and Warpage**” being submitted by **Mr. Sagar Kumar** to the **Malaviya National Institute of Technology, Jaipur** for the award of the degree of **Doctor of Philosophy** is a bonafide record of original research work carried out by him under my supervision in conformity with rules and regulations of the institute.

The results contained in this thesis have not been submitted, in part or in full, to any other University or Institute for the award of any Degree or Diploma.

**Dr. Amit Kumar Singh**

Assistant Professor

Mechanical Engineering Department

Malaviya National Institute of Technology, Jaipur

Jaipur-302017, India

Place: Jaipur

Date:

## **Acknowledgement**

I would like to express my deep and sincere gratitude to my thesis supervisor, Dr. Amit Kumar Singh, for his invaluable guidance and support. He is an excellent teacher and his knowledge and logical way of thinking has been of great value for me. This research is impossible without his inspiring guidance, experience, and subject knowledge.

I also take this opportunity to express my heartfelt thanks to the members of Departmental Research Evaluation Committee (DREC), Dr. Amar Patnaik and Dr. Harlal Singh Mali, who spared their valuable time and experiences to evaluate my research plan and the synopsis. I would also like to thank Prof. G. S. Dangayach, Head of the Mechanical Engineering Department, and his office team for helping in all administrative works regarding the thesis.

I also like to convey my heartfelt gratitude to seniors Dr. Chitresh Nayak, Dr. Kailash Chaudhary and Manoj Gupta for sharing their valuable knowledge. I also like to thank my friends Vimal Kumar Pathak, Prashant Athanker, Ramanpreet Singh, NRNV Gowripathi Rao, Chandramani Goswami and Gaurav Kumar Badhotiya for their support and help which was extremely needed to complete my work successfully. Finally, but not the least I am very thankful to my parents, my brothers and my wife Ritu Shree who have surrendered their priority and time for me.

**Sagar Kumar**

Malaviya National Institute of Technology, Jaipur

## ABSTRACT

Traditional tool making in the case of plastic injection molding is time consuming, expensive and creates a lot of waste. Recent developments in rapid tooling technology by implementing the use of advanced manufacturing process like additive manufacturing (AM) is of large significance to the industry. In the same context, this thesis aims to provide an initial feasibility study to examine whether the polymer rapid tools are realistic and can be used as practical injection mold without any major downsides. In addition, prime objective of the research is to determine whether different benchmark features can be molded repeatedly on the proposed polymer rapid tool.

Understanding the tool survivability is a critical issue that need to be verified for the tooling to be successful. The tool survivability is analysed using simulation and experimental study in this thesis. The research work begins with investigating initial feasibility on determining whether room temperature vulcanizing (RTV) and polymer rapid tool (PRT) can be used as functional injection mold tooling. Initially, simple geometric shapes were formed and studied, which represent commonly molded features. This was followed by the molding of more complex and commercially available plastic components. The result shows that the parts fabricated using soft tooling RTV shows lot of shrinkage and also it will be not useful for high temperature injection molding. The complex features are difficult to be built as there is chance of breaking the part. Moreover, the Polyjet polymer mold shows better results as compared to soft tooling in terms of shrinkage. Experimental results showed that the mold was cracked initially possibly due to increase in pressure. But after optimizing the parameters the parts fabricated shows good quality results.

Furthermore, the digital ABS material is analysed for checking its feasibility in injection molding applications. The mechanical properties of the samples were considered and further bending, tensile and impact tests were performed by measuring their hardness. In addition the physical characterization was also performed. The outcome of the results are positive and showing that different parts can be manufactured using a commercial injection molding machine with digital ABS inserts in absence of any

catastrophic failure for the typical shape, molding compound and injection times used in this study. After 50 trials, the cavity undergo a slight and permanent distortion, but the quality of the surface was virtually unaffected and the surface remains same as its original quality. Thus, Digital ABS expresses good surface and dimensional stability at the time of injection process. Initially, there is a small increase in tension as well as modulus that is expected as point out by the outcome of other studies. Further, the impact strength increased by 30% or more, which was a conspicuous improvement.

Next study was performed to investigate whether the standard benchmark features have any effect on the dimensional behaviour of the parts fabricated using injection molding. Therefore, twelve standard benchmark CAD model were selected with different geometric attributes. Subsequently, simulation analysis was performed on all CAD model using Moldflow® (MFA) simulation software. Additionally, regression analysis is applied to identify the effect of injection molding parameters on the volumetric shrinkage of part made using rapid tooling mold insert of digital ABS material. It is found that maximum volumetric shrinkage (18.75 %) is observed for square pyramid frustum, conical frustum, and solid torus. On the contrary, hollow rectangular prism shows minimum shrinkage effect having 12.61 % of volumetric shrinkage. Further, this study is extended for complex feature component, and the results are experimentally validated with contactless laser-scanning systems.

The last stage of the thesis presents an integrated methodology for developing mathematical models and predicting the values of shrinkage and warpage by correlating them with process parameters of plastic injection molding process for making the case study part i.e. electronic relay of PBT and PET polymer material. The parameters considered for the prediction of shrinkage and warpage are Melt temperature, Packing temperature and Packing time. To find the optimum value of process parameters, the analytical model using regression analysis was developed. To further improve the optimum values a recently developed modified particle swarm optimization algorithm was used.

### **CHAPTER-1 BACKGROUND & MOTIVATION**

1. Introduction	1-3
1.2 Background	4
1.2.1 Rapid tooling and its history	4-5
1.2.1.1 Direct Tooling	5-6
1.2.1.2 Indirect Tooling	7
1.3 Additive manufacturing	8-9
1.4 Reverse Engineering for part inspection	10-11
1.5 Thesis Statement	12
1.6 Thesis Organization	12-14
1.7 Chapter Summary	14

## **CHAPTER-2 LITERATURE REVIEW**

2.1 Rapid tooling techniques used for production of parts in injection molding	16-18
2.2 Use of cooling channels and additive manufacturing techniques for improving part quality	19-22
2.3 Material Jetting process	22
2.4 Directed Energy Deposition	23-24
2.5 Powder Bed Fusion	24
2.6 Binder Jetting	24-25
2.7 Vat photopolymerization	25-26
2.8 Sheet Lamination	26
2.9 Material Extrusion	26-28
2.10 Injection molding process parameter selection and optimization	28-30
2.11 Advances in 3D scanning systems for quality inspection	31-34
2.12 Discussion on mechanical and physical properties of mold in injection molding	35-37
2.13 The Knowledge Gap in Earlier Investigations	37-38
2.14 Research objectives	38-39
2.15 Chapter summary	39

## **CHAPTER-3 MATERIALS AND METHODS**

3.1 Investigations of Room Temperature Vulcanizing (RTV) soft tooling as functional injection Molding	40
3.2 Experimental set up	40
3.2.1 Selection of Test pattern (Model)	41

3.2.2 Entry Level Additive Manufacturing (ELAM) for generation of RP pattern-	41-42
3.2.3 Selection of RTV Silicon compound	42-43
3.3 Methodology to prepare RTV silicon rubber mold	43
3.3.1 RTV Mould preparation	44
3.4. Pattern by Wax injection	44
3.5 Process parameters for the production of wax patterns	45-46
3.6 Experiment and Observation	46
3.7 The responses	47
3.8 Results & discussion	48-51
3.9 Investigation of FDM modeled Polymer Rapid Tooling (PRT) for Plastic Injection Molding	51-54
3.10 Methodology to develop PRT mold	54
3.11 Material selection and properties	55
3.12 Working principle of Polyjet Direct 3D printing	56-57
3.13 Hand Injection Moulding machine to develop the part	58-60
3.14 Reverse engineering to check the accuracy of RP	61-65
3.15 Chapter Summary	65

**CHAPTER- 4 MECHANICAL AND PHYSICAL CHARACTERIZATION OF  
DIGITAL ABS**

4.1 Sample geometry and used materials	66-67
4.2 Mould inserts materials	67
4.3 Design and manufacturing of mould	68-69

4.4 Process parameter and material selection for injection molding experiments	69-72
4.5 Dimensional and Surface analysis	73
4.6 Mechanical and DSC analyses	73-76
4.7. Results and discussion	76-81
4.7.1 Mechanical properties and Crystallinity	81-83
4.8 Chapter Summary	83

## **CHAPTER-5 VOLUMETRIC SHRINKAGE ESTIMATION OF BENCHMARK PARTS**

5.1 Design and development of benchmark feature component	84-85
5.2 Material selection and properties	85-87
5.3 General considerations for design of standard benchmark parts	87-88
5.3.1 Geometric Attributes consideration	91
5.3.2 Volume Ratio (VR)	91
5.3.3 Thickness Ratio (TR)	91
5.3.4 Draft Angle Ratio (DR)	91
5.3.5 Part Weight Ratio (WR)	91
5.3.6 Quality Prediction Ratio (QR)	92
5.3.7 Cycle Time Ratio (CTR)	92
5.4 Mold design for standard benchmark parts using Autodesk inventor 3D modeling software	93
5.4.1 Design procedure to generate a core and cavity	93
5.4.1.1 Procedure to create the patching surface	93-96

5.5 Moldflow Simulation Results and Analysis for the Benchmark Parts	96-101
5.6 Result and discussion	102-103
5.7 Chapter Summary	103-104

## **CHAPTER-6 VOLUMETRIC SHRINKAGE AND WARPAGE ESTIMATION OF COMPLEX PARTS**

6.1 Development of Core and Cavity for complex feature component	105-106
6.2 Design of injecting plastic part	106
6.2.1 Best gate location	107
6.3 Employed parameters	107-108
6.4 Simulation study for PBT and PET materials	108-110
6.5 Taguchi method	111
6.6 Analysis for injection molding	111
6.7 The obtained values from the analysis	112
6.8 Regression analysis method	112
6.9 Warpage and shrinkage analysis for results evaluation	113-117
6.10 Experimental verification	118
6.10.1 The evaluation of rapid tooling by developing the test mold	118
6.10.2 Manufacturing of the rapid tooling mold by polyjet technology	118
6.10.3 Process parameter and Material selection for Injection molding Experiments	119-121
6.11 Comparison of the outcome of simulation results with experimental data using 3D scanners	121-122
6.12 Scanning methodologies	122

6.12.1 Environmental Conditions	122-123

# CHAPTER-1

## BACKGROUND & MOTIVATION

### 1. Introduction

The manufacturing scenario of the today's twenty-first century is continuously evolving into one of the volatile consumer markets with fast moving product technologies. These continuous changes are forcing the industries to be competitive along different front including design, manufacturing, quality, inspection etc. Historically, the manufacturing sector has not been at best but it has assured of providing better results in the coming days. In the last few years, the rapid growth in the manufacturing technologies and their applications has given rise to the production of complex profile parts with improved accuracy. In addition, the market globalization has forced the manufacturing scenario to be extremely competitive and volatile. To survive in such a volatile scenario, it is expected for the manufacturing industries to not only producing high quality products but also look into the aesthetics, cost as well as customer desires. In order to achieve these goals, manufacturing firms are required to adopt flexibility in their production system and reducing the time to market for their products.

Nowadays, to accomplish the objectives, reducing cycle time and for faster product development, injection molding with rapid tooling is adopted in industries. Injection molding is one of the most extensively applied and established processes in current manufacturing scenario. The process commences from the heating of a thermoplastic material which is further enforced into a mould impression under pressure. The material inside of the mold cavity cools, solidifies, and is then removed as a developed product. The moulds are also referred to as a tool which helps the resin to get the required shape and are typically machined from metals such as aluminum, hardened steel, and various copper-based alloys (Lebrun et.al., 1996) for improved and longer tool life.

Injection molding has been the most common technique for producing plastic product due to high efficiency and manufacturability. The Plastic injection molding primarily consists of three processes: filling and packing, cooling and lastly ejection. Among these three processes cooling step is the most important stage as it not only affects the quality of the product, also the productivity gets hampered. The cooling process account for nearly two-third of the total time taken by the injection molding product cycle. To improve the efficiency of the cooling stage, an effective cooling system is required. An efficient cooling channel can be incorporated to reduce the internal stresses and differential shrinkage by providing appropriate cooling the entire part. The cooling system during their design also needs to keep in mind the manufacturability of the system for controlling construction cost.

**Figure 1.1** Line diagram of Injection molding process

The other method to improve the final part quality is by means of rapid tooling. The traditional tool making is time consuming, expensive and produces a great deal of waste. The conventional tools may take lot of time to produce and can be very costly. For fabricating such tools, highly skilled and expertise personnel are required. In addition, mostly the parts are fabricated at distant places from the places where they are planned to be used, thus requiring expensive and lengthy transportation. The summation of all these problems, in the initial stages of producing a new component, the design of the developed mold leads to some changes. The changes are due to the modifications in the product's

dimensions or because of mold refining to better meet desired part specifications. Whatever may be the reason for these changes, each modification needs extensive and expensive alterations. In few cases, the changes incorporated in the mold are so severe that it is advisable to reproduce it from scratch.

The injection molds are expected to produce components that are near to their original specifications. The mechanical properties, thermal conductivity and accuracy of the mold have a substantial impact on part quality, geometric complexity, molding cycle and competitiveness (Lee & Subramanian, 2007). However, for producing prototyped components or mold verification, the major and primary cost is driven by the cost of the mold. To improve the effectiveness, productivity and compress the mold cycle of the injection molding process, one of the possible alternatives to conventional tooling in those instances is Rapid Tooling (RT). RT generally, is the term proposed for either indirectly or directly exploiting a 3D printed prototype as a tooling part (Sachs et.al, 1992). Moreover, a rapid tool is a mold which can fabricate similar products as a traditional tool, at significant good quality; however, it must be fabricated within a small amount of time and expense. These tools are not used to completely replace the traditional tooling methods nor will they be used for producing components in high volume. In contrast, the RTs are ideally used for prototyping the products and for short batch run applications which necessitate maximum flexibility. There are numerous approaches available for creating rapid tools.

The most recent approach involves the application of Additive Manufacturing (AM) process. Usually, the AM route was applied for developing the injection mold indirectly. Though, the most ideal use for AM-produced rapid tools is their direct use as a functional injection mold. The success of some of the AM techniques resides on the adequate availability of materials. With ever increasing progress in the developments of new AM materials and techniques, it may now practical to fabricate plastic molds and apply them in the form of functional tools. Moreover, the thermal behaviors of plastic molds are also different from the conventional metal molds. The present research work aims for an early feasibility study to determine whether the rapid tools based on different polymer are possible as injection mold tools by analyzing and determining if they can produce specified dimensions over different cycles.

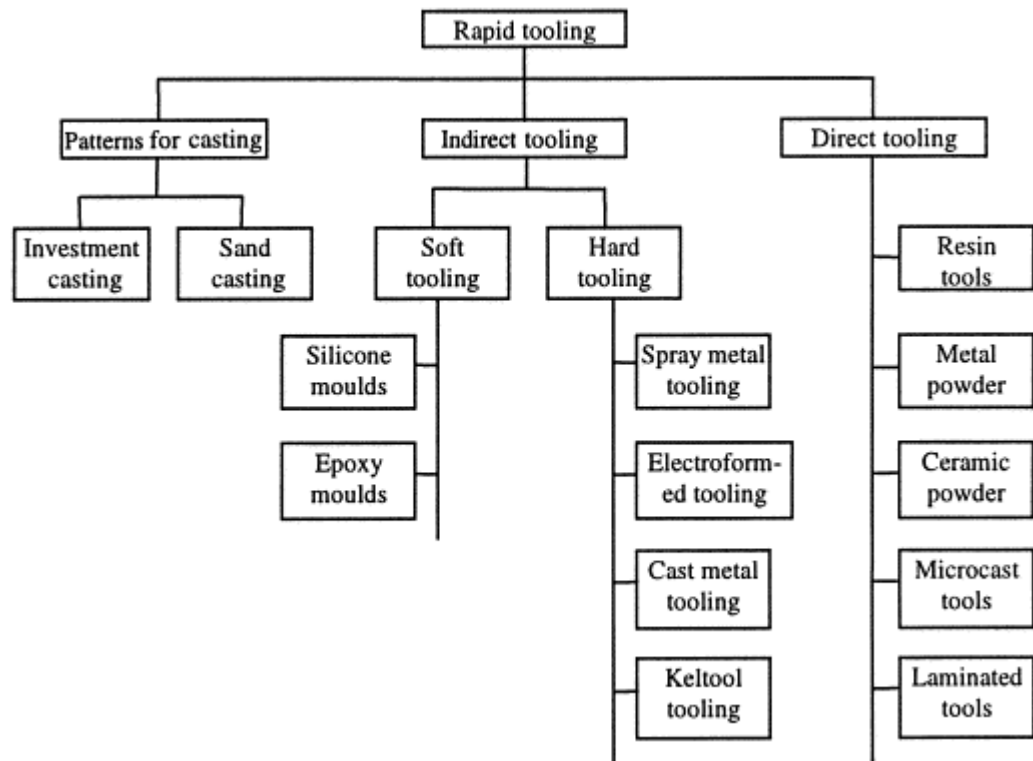

## **1.2 Background**

This section provides a brief overview of the subject matter and terminology normally used within this research. The subject matter includes rapid tooling history, additive manufacturing for pattern making, injection molding and the use of rapid tools within the injection molding.

### **1.2.1 Rapid tooling and its history**

Till late 1990s, the rapid tooling always has the requirement of conventional and customized tools such as jigs and fixtures. In addition, the hardware and moulds are also used for pervasive injection molding and die manufacturing within the rapid tooling scenario. The moulds are earlier developed using expensive and time taking subtractive manufacturing processes, depending on the complexity of the part. Moreover, there is limited flexibility for further improvement and any error in the manufacturing of such object may lead to the increase in cost of product cycle. In contrast, with the advent of 3D printing technology, the moulds are printed in short period of time by additive manufacturing (AM) process. In comparison to conventional tooling practice, the mould preparation using 3D printing involves less cost and less time (Bassoli et.al, 2007; Ferreira, 2004 and Hofmann, 2014)

The different rapid tooling processes available are classified and shown in Figure 1.2. Earlier, the researchers have classified the RT process based on the quantity of parts produced, cost and time taken by conventional tooling (Chua et.al, 2015; Mueller & Kochan, 1999; Levy et.al, 2003). In context of tooling, mainly plastic injection

**Figure 1.2** Classification of rapid tooling (Rosochowski & Matuszak, 2000)

molding tools are considered, as these are commonly used forming tools. The rapid tooling options may also be classified based on the material quantity and the amount of quantity required as shown in Figure 1.3. It is quite clearly evident that for strong technical parts with more number of quantity, more refined tooling option has to be considered. The choice of selecting the adequate rapid tooling technique solely depends on the requirement of quantity, its quality and time to produce components. Moreover, skill and expertise are important tools that are required for effective selection of rapid tooling processes.

### 1.2.1.1 Direct Tooling

Direct tooling referred to as process in which an AM part can be directly used as mold or pattern. The part manufactured using additive manufacturing doesn't require any post processing ideally and can be directly used in production floor for fabrication of product

at a rapid pace. Since the inception of this concept, it has not been widely accepted in industries as a main scale

**Figure 1.3** Relations in material quantity of parts and selected RT technique (Hilton, 2000)

manufacturing technology. The direct tools generally made of durable material and used to produce larger number of components. Spray metal tooling is used as tooling for low pressure processes. In recent years, with the development of spraying methods and technologies, it is preferred as tooling for injection moulding prototypes of low production. Cast metal tooling is widely used in injection moulding and die casting.

Ceramic tooling is applied for producing more accurate components which are precise in their size and dimension with minimum shrinkage. Further, metal powder tooling is extensively used for direct tool production. Usually, the automotive components are fabricated from this type of tooling that requires maximum tensile strength. The use of laminated metal sheets is widely accepted but only drawback is to keep in mind to resolve the bonding technique to ensure structural integrity.

### 1.2.1.2 Indirect Tooling

The indirect tooling refers to the process in which a model is build using an RP method, in any suitable material that is not required to be metallic. Using the master pattern, a mould is developed out of a certain specific material such as soft metal, silicone rubber and epoxy resin. It is broadly divided into two primary groups' i.e. soft tooling and hard tooling depending on the type of component and the number of quantities required for production. Soft tooling refers to the low cost and soft material process which is used interchangeably. Mostly, the parts produced in RT are using soft tooling techniques. One example of soft tooling is use of silicon rubber for producing mould cavity about a master rapid prototyping pattern as shown in Figure 1.4. The various other examples of soft tooling include epoxy molds and castable ceramics.

**Figure 1.4** Example of silicon rubber soft tooling

Though the use of soft tooling is widely accepted in industries but the shift is now beginning to change to use hard tooling. These tools are widely used for short prototype runs especially 100-200 parts batch production (Jamal et.al, 2004). The principal

advantage of direct tooling comes as the production of injection molding bridge or “firm” tools.

### 1.3 Additive manufacturing

Additive manufacturing (AM) is also well-known by the names of layered manufacturing (LM), freeform fabrication (FFF), rapid prototyping (RP), and automated fabrication. RP is an advanced technology useful in developing physical models at a rapid pace and fabricating functional prototypes in small batches directly from a virtual computer aided design (CAD) model. It involves addition of material sequentially layer by layer until a complete 3D object is fabricated. The AM processes developed part by addition of material, in contrast to removing material as performed in conventional manufacturing processes. Therefore, it helps in minimizing the wastage of material as compared to the traditional manufacturing. Usually, the AM techniques work by splitting the computer model into similar cross-section layers. The buildup of these layers from bottom to top created a physical object (see Figure 1.5).

**Figure 1.5** Layer by Layer depositions to build a product (Prest et.al, 2013)

The various AM technologies are commonly similar to each other by adding and joining materials in layer-wise method to form the objects. This is directly contrary to the

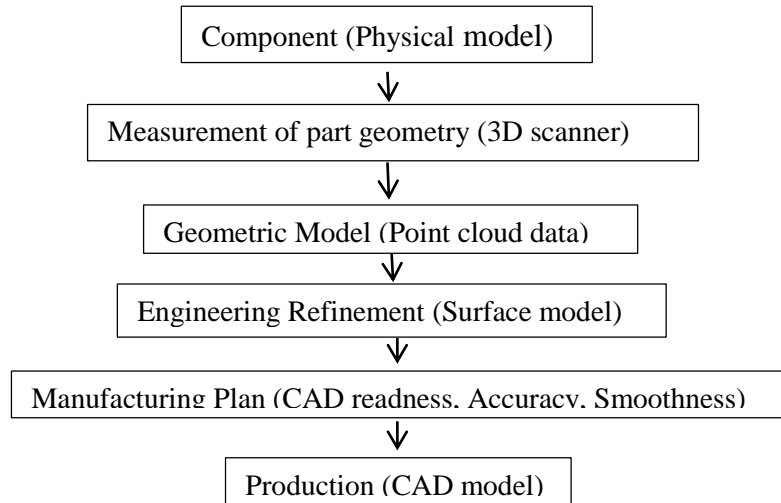

classical techniques such as milling and forging. Prior to that, objects are made of mechanical removal of material, and later mechanical forces, the material is constantly deformed in the desired form. The beginning for each RP process is the cause of the abstract geometry of the object being created. From this, a record must be created that describes the geometry. The created record must be manipulated to produce the instructions needed to control the process in the final phase of the actual manufacture of the component. The input at the beginning of the RP process may be a point cloud obtained by sampling techniques (Reverse Engineering) or 3D CAD models produced by many solid modelers or mathematical data acquired by analytical equations. The entire process of creating an object by any RP method can be classified into two stages (Shirazi et.al, 2015 and Stevenson, 1993).

STEP 1: At this stage STL (stereolithography) file is created with tessellating 3D model, that is cut and retained, and the generated data is stored in standard formats that can be interpreted by RP machines. This information will be used in step 2. At this stage, the most important parameters are the choice of the orientation of the parts and the layer thickness, since the construction time, the surface quality, the number of supporting structures; the costs etc. are affected by them.

STEP 2: In this step, a physical model is generated. This step is different for the processes of RP and depends on the basic principle of deposition used in the RP machine. The software operating the RP system generates laser scan paths (in processes such as selective laser sintering, stereolithography etc.) or material deposition paths (in processes) such as fused deposition modeling from the slice information obtained in step 1. At this stage, various process-related information such as tolerance (surface finish), material, machine (such as laser spot diameter, cutting speed, temperature, etc.) is provided (Badrinarayan & Barlow, 1994; Dalgarno & Stewart, 2001). There are several known RP technologies available on the market, including only a few stereolithography (SL), selective laser sintering (SLS), laminated object production (LOM), fused deposition modeling (FDM), 3D printing (3DP), multi-jet modeling (MJM) and Solid Ground Curing (SGC) (Bassoli et.al, 2007; Bernard et.al, 2002, Cheah et.al, 2005).

**1.4 Reverse Engineering for part inspection** - Although a traditional engineering process initiates with a design concept, in contrast reverse engineering begins with capturing the data of actual shape of an object. The major advantage of the reverse engineering process is data capturing of the free-form surface. It is imperative to capture the shape point data of physical object. The accuracy of the reconstructed model largely depends on the quality, type of the data captured and type of measuring instrument. In industries, till date part inspection was performed mostly by gauges, templates and Coordinate measuring machines (CMM). However, in recent times the conventional gauges and CMMs are replaced by 3D scanners because of their improved accuracy and fast data acquisition (Galantucci et.al, 2003; Gao et.al, 2006; Onuh et.al, 2006) In addition, the CMMs are also not suitable for measuring soft materials; also the sampling speed is very low. The steps for the reverse engineering process consist of measuring part geometry through a contact or non-contact instrument, developing a computer-aided geometric model from the measurement data and possible technical refinements of part design, developing the manufacturing plan, selecting the materials, and finally becoming the real one Production model developed. The basic flow of reverse engineering process is shown in figure 1.5.

Reverse engineering with 3D scan data is a rapid and efficient way to generate CAD models when an object has a complex structure or when a 3D model does not exist for an object. The 3D scanning device takes the physical geometry of the component and converts it into 3D digital model. The mechanism of laser scanner used in this work is shown in Figure 1.7. The 3D laser scanning process begins with laser line projection on the surface of the object. The laser beam is reflected and CCD sensor is placed to capture surface data in the form of 3-dimensional point data.

**Figure 1.6:** Flowchart for basic phases of reverse engineering

The point data of object surface is acquired using triangulation method. Scopes of an object are scanned simultaneously so that hundreds or thousands of closely positioned points can be captured simultaneously. Without making the contact with the object the process of laser scanning is performed.

**Figure 1.7** Schematic of 3D scanner mechanism

For rapid product development (RPD) newly established equipment and techniques are used that support the designers and manufacturers in surviving the demands for the reduction of product development time. For example, injection molding companies need

to dramatically reduce tool and development times for die. By introducing the reverse engineering methodology, a three-dimensional product or model can be quickly tested in digital form, re-modeled and exported for rapid prototyping or rapid tooling or for rapid manufacturing.

### **1.5 Thesis Statement**

This thesis presents the practical applicability of digital ABS mold and inspection of developed specific feature component followed by a regression model. The main objective of the research is to improve the quality of the part through optimizing process parameter of a plastic injection molding machine followed by a 3D inspection process, beginning with manufacturing to the final model developed. During the injection molding process, the analysis of rapid tooling mold on the dimensional and surface stability and the final casting process is studied in detail. The CAD model is used for analysis with Moldflow software. The mechanical and physical properties of the samples were analyzed by tensile, bending and impact test as well as by measuring their hardness. Further, a framework for systematic methodology is developed to determine optimal injection molding conditions for minimum shrinkage and warpage in a thin wall relay part for Polybutylene Teraphthalate (PBT) and Polyethylene terephthalate (PET) materials using newly developed Modified Particle Swarm Optimization (MPSO) algorithm.

### **1.6 Thesis Organization**

The rest of this thesis is organized as follows:

#### **Chapter 1: Background and Motivation**

The background, motivation and importance of research to develop most ideal use for AM-produced rapid tools is their direct use as a functional injection mold for effective and accurate industrial applications are presented in this chapter. It also emphasizes the contours of the dissertation organization.

## **Chapter 2: Literature review**

This chapter presents a literature review on various challenges and issues related to PRT mold, followed by Injection molding machine operated at optimal process parameter for data collecting and verifying the results by 3D scanning system. The discussion is followed by volumetric shrinkage and warpage error evaluation and optimization method for effective inspection of developed part and mold.

## **Chapter 3: Materials and methods**

This chapter includes the selection and employability of materials for the use of functional injection mold tooling. The main purpose of this study was to determine whether the Room Temperature Vulcanizing (RTV) and Polymer Rapid Tooling (PRT) mold could develop a distinctive feature for specific geometry within the acceptable tolerance limit and can perform this repetitively. Initially, it was created and studied by simple geometric shapes, which represent the most commonly developed features. Further this was followed by the molding of more complex feature component.

## **Chapter 4: Mechanical and physical characterization of Digital ABS**

The present study deals with the analysis of digital ABS on dimensional and surface stability as well as the final casting properties. The mechanical properties of the samples were analyzed by measuring bending, tensile and impact tests and their hardness. Differential scanning calorimeter (DSC) was used to measure PET crystallization.

## **Chapter 5: Volumetric Shrinkage Estimation of Benchmark parts**

The work of this chapter proposes an effective shrinkage estimation of twelve reference benchmark features commonly used in an injection molded plastic component. To determine the influence of shape and geometry parameters on volume shrinkage and warpage, a systematic methodology based on Moldflow® (MFA) software is used. Furthermore, a statistical regression technique was used to identify the percentage contribution of geometrical attributes to volumetric shrinkage and warpage. The regression equation followed by geometric parameters was developed to estimate the percentage of volumetric shrinkage of injected part.

## **Chapter 6: Volumetric Shrinkage and Warpage Estimation of Complex Parts**

This chapter deals with the study of volume shrinkage and warpage results for complex parts that consist all the benchmark features. For this purpose an electronics component relay is considered as a sample produced from digital ABS mold integrated with straight cooling channels. A systematic methodology is proposed for analyzing volumetric shrinkage and warpage in an injection molded part having a thin shell structure during the injection molding process. The outcomes were experimentally validated with reverse engineering technique.

## **Chapter 7: Optimization of rapid tooling molded Complex featured component**

This chapter discusses a systematic methodology for analyzing volume shrinkage and warpage in an injection molded component with a thin shell structure during the injection molding process. First, the impact of parameters of the injection molding process on shrinkage and warpage for various wall thicknesses was investigated using the Taguchi method. The shrinkage and warpage values were found by Moldflow insight software. The result of confirmation experiments and analysis of variance (ANOVA) ensures that the quadratic models of the shrinkage and warpage are well fitted with the values simulated at optimal values. The shrinkage and warpage are examined and predicted by the mathematical model obtained for the individual influences of all parameters.

## **Chapter 8: Conclusion and Future Scope**

The results of this study are summarized in this chapter. It also deals with the contribution and the future directions of this research.

### **1.7 Chapter Summary**

This chapter begins with a background followed by a brief introduction of rapid tooling, its applications and advantages. Further reverse engineering principles with its importance in industrial applications is discussed. The significance of rapid tooling for inspection in industries is presented. The motivation behind developing an iterative and detailed inspection plan is presented here. At last, brief information about various chapters is discussed.

# CHAPTER – 2

## LITERATURE REVIEW

This chapter presents an extensive literature survey which provides background information on the research topics of the present investigation. Since, the present work emphasis is on the rapid tooling and the parts produced using additive manufacturing mold, this chapter summarizes overview of different rapid tooling techniques used in production, additive manufacturing (AM) techniques, injection molding process parameter selection, optimization and advances in 3D scanning systems for quality inspection. Furthermore, the discussion on mechanical and physical properties of additive manufacturing mold is also been performed. The topics briefly reviewed all the relevant literature and still needs further research to minimize the above covered challenges and issues for industrial applications.

The literature was classified on the following basis:

- 2.1** Rapid tooling techniques used for production of parts in injection molding
- 2.2** Use of cooling channels and additive manufacturing techniques for improving part quality
- 2.3** Injection molding process parameter selection and optimization
- 2.4** Advances in 3D scanning systems for quality inspection
- 2.5** Discussion on mechanical and physical properties of additive manufacturing mold

At the end of this chapter, an overview of the literature survey and a knowledge gap in the previous investigations are presented.

## 2.1 Rapid tooling techniques used for production of parts in injection molding-

Since early 1990's, several attempts have been made for producing parts in injection molding using rapid tooling. The prime objective of applying rapid tooling concept is to reduce the product lifecycle and producing faster product in injection molding (Levy et al., 2003). With the use of rapid tooling, the tool delivery time can be reduced upto 50%. Past studies suggests that metallic rapid tools are widely applied rapid tools in injection molding for production of components. There is number of research available that shows the successful implementation of metallic material for rapid injection mold development (Rosochowski & Matuszak, 2000). Initially, the rapid tooling involves the use of Direct Metal Laser Sintering (DMLS) additive manufacturing technology. The strength of the sintered mold was increased by bonding together the powder particles using oven heating (Dalgarno & Stewart, 2001). The DMLS techniques were used to produce metallic molds using different alloys material involving steel, aluminium, zinc and titanium etc (Barlow, Beaman, & Balasubramanian, 1996). These RT techniques are used for producing the conventional hard molding tools which are further useful in producing parts in full time production. Based on past publications data, it was found that the DMLS rapid metallic tools are capable of producing 250 to 1000 parts. In addition, the metallic mold fabrication takes three to four weeks in mold fabrication (Pham, 2000). Similar work reported on DMLS process used the mold which is built on a steel plate for facilitating mold assembly.

**Figure 2.1** Schematic of DMLS technique (Barlow, Beaman, & Balasubramanian, 1996)

By implementing the similar techniques metallic powders are also sintered to form loose sponge. After successful sintering process, the sponge matrix is allowed to permeate with a known alloy by means of a vacuum method. The aforesaid methods develop the molds or tools that have the capabilities of firm tooling or more advanced. Nevertheless, this process involves the need of post processing operation for removing the porosity from the initial prototyped model in metal that also takes a percentage of lead time and expense (Badrinarayan and Barlow, 1994).

Another method available in literature for creating paper-based prototypes, based on the laminated object manufacturing (LOM) principle, which has been used for making metallic laminated tools and parts (Dickens, 1997). This process requires the bolting of metal sheets together in place of glueing or brazing. Therefore, there is an absence of complete adhesion between the layers making it unsuitable for injection molding processes involving liquid metal as material. Moreover, the LOM process has an intrinsic incapability of adaptive layer thickness and in addition suffers from excessive wastage of material (Bryden et al., 2004).

**Figure 2.2** Metal mold used in injection molding (Dickens, 1997)

Furthermore, distinctive droplet producing processes have been developed that includes welding, thermal spraying and micro-casting for creating metallic tools to enhance the deposition eminence and to achieve the defined profile shape and size (Spencer et al., 1998). The other commonly investigated technique involves spraying of metallic particles that are highly energized (Krunakaran, 2004). This process is quite alike in its procedure

to ink jet printers. The method produces highly inflexible and thermally active tools of firm tooling abilities. Depending on the size of the developed metallic tool and their intricacy, hard tooling status can be attained. The major shortcomings of all the aforesaid methods are that accessibility of metals is limited as compared to the part produced by plastics materials. In addition, the components build up using metallic materials are expensive in contrast to plastic components.

Moreover, the machines use to develop metallic tools and parts can cost twofold times the amount of a substitute machine. An additional drawback is that metallic-based AM technologies have very limited build volumes, due to the restrictions in size of build volume and tool. Several other attempts have been made for producing the polymer rapid prototype as an injection mold tool. In the mid 90's, (Jacobs, 1996) a modified Stereolithography technique is implemented using epoxy solid style of rapid tooling. The epoxy's mold has the ability to run for more number of cycles as compared to traditional resin mold tool. The polymer molds are beneficial in the way that only a fraction of cost is incurred in their development in comparison to metal molds (Dickens, 1997). The initial phase of polymer mold involves the use of SLA resin which is very soft to resist the amount of heat at high temperature and pressure in the injection molding process (Dickens, 1997). Therefore, the dimensional tolerances of the parts developed are of great concern as the shape and dimensional sizes will change as the pressure and heat increases or decreases (Dawson, 1998).

Furthermore, one important study carried out by (Palmer & Colton, 2000) found that some shearing action will take place in mold and results in failing mainly depending on the directionality of the resin as mold cavity is filled in. The aforementioned problem in the SLA mold results in infeasibility in its use for industrial applications. During the last decade due to technological growth in developing new materials and polymers, it has now become quite easy to develop material of highest strength and low heat deflection properties. Due to the rapid advancement in materials development along with expansion of entry level (low cost) polymer-based-AM machines, the use of polymer rapid tool for developing injection molds would be more beneficial choice for batch and highly flexible production. Moreover, very few past studies have been performed to conform the use

polymer based rapid tooling. The present thesis will be the extension of the work on the suitability of polyjet printed rapid tooling mold.

## **2.2 Use of cooling channels and additive manufacturing techniques for improving part quality**

With the improvement in manufacturing technology and intricate profile, the need for using the polymer injection molding is increasing day by day. Appropriate thermal management of injection molding tooling is important for accomplishing concurrent enhancements in production rate and part quality (Sachs et al., 2000). The cooling channels generally manage to flow out heat outside of the plastic mold. Generally, the conventional cooling channels are machined using a straight line approach. The conventional methods provide unpredictable results as the cooling throughout the mold are not reliable and accurate. Due to non-uniformity in cooling along different parts leads to extended cycle times, also uneven cooling can happen, warpage and scrap also produced. A significant reduction in the manufacture time of a plastic part collected to an improved product quality is expected with the use of conformal cooling channels (Dimitrov and Moammer, 2010). The cycle time and cooling time can be effectively reduced in an injection moulding by optimum utilization of cooling channels (Dalgarno and Stewart, 2001).

Although, a number of past research are available that deals with the design and modeling of conformal cooling channels in injection molding tooling, the concept of conform tooling design is not so deep-rooted. Conformal cooling channel shows a possible alternative with increasing acceptance (Hall and Krystofik, 2015). The schematic of traditional cooling channel and conformal cooling channel is shown in Figure 2.3. The major benefit of using conformal cooling channel is that it minimizes the cooling time and provides uniform cooling. In comparison to traditional straight cooling channels conformal one has proved to be more effective than the conventional cooling channels in terms of a rate of production and accuracy of molded parts. In addition, greater surface area for the cooling in conformal cooling channel as compared to the conventional straight-drilled cooling systems, resulting in unvarying circulation of heat. Some of the geometrical features needed in conformal cooling channel are very difficult to

manufacture using conventional machining or manufacturing techniques. For the aforementioned reasons rapid tooling (RT) techniques are best suited for the fabrication of conformal cooling channels.

**Figure 2.3** Conventional and Conformal cooling channel (Dimitrov and Moammer, 2010)

Past studies performed by different researchers depicts the advantages of the cooling channels in plastic injection molding. Au and Yu, (2007) in their study suggested a scaffolding design for conformal cooling channel fabrication. The study also performed the comparison of the mold cavity by incorporating and removing the scaffolding assembly using virtual simulation procedure (Figure 2.4). The Moldflow plastic insight interface was used and porous scaffolding structure was investigated. The results of the study concluded that the scaffold cooling structure provided improved cooling inside the mold cavity. One similar study (Hearunkyaji et al., 2014) was performed that applied the concept of fins for improving the efficiency of cooling channels. Furthermore similar studies were presented by Saifullah ABM and Masood, (2007), they performed simulation for comparison in between square cooling channel and straight cooling channels. Their results confirmed that the conformal cooling channel reduced the cycle time as well as cooling time significantly in contrast to traditional straight cooling channels. Another similar study conducted by Park and Dang, (2010) used Moldflow software for simulating the behavior of cooling channels with baffles for radiator grills using ABS polymer. After the significant analysis and comparison with straight cooling

channels, the baffled cooling channel provided much better temperature variation which is comes out to be significantly uniform.

**Figure 2.4** Mold cavities with and without cooling channel (Au and Yu, 2011)

In other comparable study, Altaf et al., (2011) investigated the effect of circular cooling channels in comparison to profiled cross-sectional cooling channel using ANSYS interface. The results showed that profiled cooling channel have improved heat flow of approximately 15 % in comparison to the simple one. One specific design was proposed by Au and Yu, (2011) with porous design that mainly based on the duality principle. The projected design delivers a more even cooling performance than the traditional conformal cooling channel design. One of the advanced studies on the design of conformal cooling channel was performed by Wang et al., (2011). They proposed an algorithm based on Voronoi diagram to modify the structure of conformal cooling channel. The conclusions indicated that the presented algorithm efficiently minimizes the cooling time and in addition maintains the temperature uniformity as well as linear and volumetric shrinkage.

Au and Yu (2014) further studied the effect of changing the distance between the mold cavities and cooling channel. This method helps in balancing the heat flow through the cooling channel starting from inlet to the outlet. One specific study performed by Khan et al., (2014) designed dissimilar types of cooling channels and studied their effects in Mold flow Advisor interface. The cooling channel used for the analysis includes conventional, series, parallel and cooling channel with additive cooling lines for cooling a food container. The results depicted that the most efficient cooling channel is the one using additive cooling and also it takes less cooling time. Similarly, Wang et al., (2015)

proposed a novel method for designing the structure of cooling channel in spiral form and then comparison is made with other cooling channels available in literature. It was found that the cooling time for spiral conformal cooling channel is less as compared to Voronoi diagram cooling channels. One of the recent study provided by Brooks and Bridgen (2016) provided the novel concept for conformal cooling channels in layers for providing high heat transfer rates and very low variation in temperature.

There are number of studies available that give the idea that for effective fabrication of complex conformal cooling channels rapid prototyping is a better alternative in comparison to traditional manufacturing techniques. The rapid prototyping techniques have been used for the development of metallic tool inserts as well as conformal cooling channels. Among them for the fabrication of complex-shaped conformal cooling channel, different RP processes are used. RP technology has been in use since the early 1980s. In 1991, various additive manufacturing processes were classified as powder-based, liquid-based and solid-based systems (Kruth, 1991). based on the different types of materials for part fabrication. Further, various AM processes and systems using a functional classification scheme has also been presented (William, 2014). The basic additive manufacturing processes are discussed in brief in the following sections;

### **2.3 Material Jetting process**

Material jetting is similar to the inkjet printing in which droplets of wax or photopolymer material are selectively deposited through an orifice to build a 3D artefact (Calvert, 2001; Gans et al., 2004; Stucker, 2012). In material jetting process, material droplets are created using two different modes: (1) Continuous inkjet (CIJ) and (2) Drop on demand (DoD). Generally, CIJ systems are used at places where high printing speed is required. In contrast, DoD is used where higher accuracy along with small droplets are required (Vaezi et al., 2013). A lot of researches have been done in the field of direct ink jetting, which suggests that different parameters and factors are responsible for improving the quality of ink jetting process.

parameters responsible for improving the quality of DED process includes powder flow rate, laser diameter, scanning rate, laser power (Laeng et al., 2000). Recent research shows that a powder material characteristic is also a key factor in improving the quality of printed part (Kakinuma et al., 2016). The prime advantage of this process is its controlling ability in the microstructure of build parts. Another advantage of this process is in improving the tribological properties of printed parts by allowing coating to the surfaces (Wilson et al., 2013).

## **2.5 Powder Bed Fusion**

Powder bed fusion process is one of the first commercialized AM processes. This process used a thermal source to melt and fuse the powder particles of metal, ceramics and polymers into the desired patterns (Stucker, 2012). Some of the most popular powder bed fusion systems known are Selective Laser Sintering (SLS), Selective Laser Melting (SLM) and Electron Beam Melting (EBM). The SLS and SLM system employs laser source while EBM uses a scanned electron beam (Kruth et al., 2005; Buchbinder et al., 2011; Murr et al., 2012). Several studies have been reported for determining the process parameters (over 50) characterizing the bed fusion processes. The process parameter can be categorized into mainly four groups namely, laser related, scan related, temperature related and powder related parameters.

## **2.6 Binder Jetting**

In the early 1990s, binder jetting methods based on ink jet technology was introduced in Massachusetts Institute of Technology (MIT) and commercialized by Z Corp. and Ex one. The process deals with printing a binder in to powder bed to build a structure. The binder droplet helps in sticking the powder material together providing desire shape to the part. Once this step is complete, it is followed by lowering the powder bed and new layer is deposited and again the above process is repeated (Sachs et al., 1992). A wide choice of materials are processed through binder jetting process such as metals (Williams et al., 2010), foundry sand (Snelling et al., 2013), ceramics (Yoo et al., 1993), and polymers (Lam et al., 2002; Leong et al., 2003; Lee et al., 2005; Tay et al., 2007).

Distinguished researchers have worked on binder jetting process involving different applications. One of the main applications include scaffold development (Sherwood et al., 2002), The prime significance of this process is fast build time of parts as very less amount of material is dispensed through orifice. Additionally, the combination of metal powder and additive in binder enables material composition not easily achieved by other AM processes (Gibson et al., 2010). However, the parts printed employing the binder jetting process have inferior accuracy and poor surface finish as compared to parts of material jetting process.

## 2.7 Vat photopolymerization

In the early 80s, C. Hull introduced first AM system commercially based on SLA process. SLA is the main photopolymer method in which ultraviolet laser is used to polymerize the UV curable resin selectively, layer by layer (Cooper, 2001; Noorani, 2006) as shown in Figure 2.6. Most of the research found for this process involves the processing of ceramics (Chartier et al., 2008; Bian et al., 2012; Chopra et al., 2012). The process of vat photopolymerization is widely used in different applications like dental fillings, ear hearing aids and scaffolds (Bartolo, 2011; Serrine et al., 2015).

**Figure 2.6** Schematic of Vat photopolymerization process (Chartrain et al., 2016)

The prime advantage of this process is its high resolution and ability to fabricate complex objects. However, main limitation of this process is its inherency to use only photopolymers. Further, some of the more problems reported by different studies includes errors caused by overcuring, scanned line shape, trapped volumes and shadowing obstruction of earlier build layers (Kim et al., 2011; Wong and Hernandez, 2012; Choi et al., 2011).

## **2.8 Sheet Lamination**

The manufacture of sheet lamination additives is the process of bonding sheets of material to form an object. There are two systems that have been commercialized are Laminated Object Manufacturing (LOM) and Ultrasonic Consolidation (UC) (Mueller and Kochan, 1999; Ram et al; 2007). Usually, the sheet lamination AM processes was used to fabricate metal parts stacking, cutting, and gluing outlined metallic laminates. In the late 1990, few studies reported the first laminated tooling sheets for sheet metal fabrication (Himmer et al., 1999). Several researchers have tried to enhance the laminated bonding (Wimpenny et al., 2003; Janaki Ram et al., 2006) with reduced stair step effects (Walczyk and Yoo, 2009).

## **2.9 Material Extrusion**

AM machines based on material extrusion deposit material through nozzle by pressure created using tractor-feed system in continuous layer form to fabricate objects. Fused deposition modeling (FDM) is among the most commonly used AM process (Wohlers, 2011). The FDM based printer was developed by Stratasys in 1988 that produced sliced layers by extruding molten thermoplastic material (Bernard and Fischer, 2002; Noorani, 2006; Kai et al., 2010). FDM process used amorphous thermoplastics for part manufacturing having acrylonitrile butadiene styrene (ABS) being the most common. The other materials available in market for FDM process are poly lactic acid (PLA), polyimide, and polyphenylsulfone.

The gradual expiring of a few valuable patents in 2009 offers a level playing field for the technology innovators to incubate, alter or harness the FDM process (Gridlogics,

2014). FDM based AM process schematic is shown in Figure 2.7. In FDM process, material is melted and flow through liquefier head and passed through the nozzle. Further, the material is deposited layer by layer as shown in below Figure 2.7. The FDM process is clean, safe, and highly automatic and also produces minimum waste. Other FDM advantages include easiness of support removal, short cycle time, and easy integration with CAD software. These features make it appropriate for variety of applications (Chua et al., 2010; Ingole et al., 2009; Elliot et al., 2013). Lately, a new trend in FDM has emerged, which can be referred to as entry level additive manufacturing (ELAM) that is comparatively inexpensive, desktop sized and usually have an open chamber (Lotz et al., 2012).

**Figure 2.7** Schematic diagram of FDM based AM process

Among the above AM technologies, mainly the powder based AM process are only used. One study performed by Donnchadha BO and Tansey (2003) used SLS method for producing tool inserts, which helped in reducing the lead time and incurred cost. Directed

metal deposition is used in one specific study for reducing the production cycle time as well as without affecting the part quality (Davis et al., 2003). One important study by MIT reveals that 3D printing based on FDM principle was used to create mold with conformal cooling channel which was further used in injection molding machine (Xu et al., 2001). In the recent study of Eiamsa-Ard and Wannissorn (2015), the authors applied metal deposition method for creating mold along with the conformal cooling channel. This thesis deals with the use of Polyjet printed mold along with conformal cooling channel in place of metal mold in injection molding application. The Polyjet printer was based on FDM principle which was very rarely used till date for mold production.

**2.10 Injection molding process parameter selection and optimization-**The plastic injections molding (PIM) processes are widely used for producing intricate shaped plastic parts with distinctive geometric features and have shorter production cycles. The PIM process is a repeated one which consists of filling and packing, cooling and ejection (Noble et al., 2014). Injection molding helps in producing products for computer, communication, and consumer electronic (3C) such as portable computers and cell phones. The 3C products are generally thin, light, short and small (Chiang et al., 2007, Chen et al., 2009). However, with the increasing demand of more complex products having less wall thickness, the PIM process is prone to face more challenging tasks (Ozcelik and Erzurumlu, 2005). Consequently, the quality of the parts produced using PIM process is affected by the appropriate selection of the various process parameters and the mold design (Liao et al., 2004, Chiang, 2007). In contrast, the inappropriate process parameter values led to produce part defects, resulting in long lead times and high cost (Hasan et al., 2007).

Warpage and Shrinkage are one of the most imperative drawbacks used to measure the quality of injection molded part. Previous studies indicate that shrinkage and warpage are mostly related to injection molding process parameters. The influence of packaging parameters and gate geometry on the final part has been studied by Leo and Cuvelliez (1996) and it was found that thinner gates obtain more uniform shrinkage in processes with the same packing pressure. Galantucci and Spina (2003) applied double skin model for investigating the warpage defect and further concluded that melt temperature was among the most influencing factor for minimizing warpage. Huang and

Tai (2001) in their study applied computer simulation and experiment for analyzing the factor affecting warpage in a thin shell injection molded components. Tang et al. (2007) applied Taguchi method for minimizing the warpage in the design of improved plastic injection mold. Similarly, Taguchi and ANOVA are used in a study for obtaining optimal shrinkage injection molding conditions (Park and Ahn, 2004). The results suggested that optimized parameter reduces shrinkage by 1.244 % and 0.937 % for Polypropylene (PP) and Polystyrene (PS), respectively.

Similarly, Park and Dang (2012) in their study suggests that runner and cooling channel geometry can improve the final quality of products. One specific study was found for minimizing the warpage in thin shell plastic parts by employing the response surface methodology (RSM) and genetic algorithm (GA). Hakimian and Sulong (2012) in their study applied Taguchi method to analyze the shrinkage and warpage in micro gears of polymer composites. Choi and Im (1999) found that residual stress is an important factor that affects the shrinkage and warpage defect in injection molded components. Liao et al., (2004) in their study provided optimum conditions for minimizing shrinkage and warpage problems. The cyclone scanner and polyworks software was used for determining the shrinkage and warpage problem. The packing pressure was found to be the most influencing factors. Kikuchi and Koyoma (1996) have applied finite element method for studying the relation among warpage, part thickness and anisotropy.

In a recent study, Othman et al., (2017) also optimizes the shrinkage and warpage in their study for composite material. In addition, effects of different process parameters are discussed in recent studies of Mohan et al., (2017). One recent study used simulation based methods for prediction of shrinkage and warpage in the injection molding process (Zwicke et al., 2017). Dan and Bistany (2000) applied RSM for examining the sink marks in injection molding lab experiments. The study includes determining the effect of different injection molding parameters like melt temperature, mould temperature, injection rate cooling time, pack time, pack pressure on final part quality. Beryllium copper as mold material was found to be effective and efficient in minimizing the sink marks.

## **2.12 Advances in 3D scanning systems for quality inspection**

From the past few years, the use of non-contact scanning devices is gaining an increasing interest in reverse engineering (RE) applications for data acquisition of real-world free form shapes, in addition to inspection purposes. These devices provide masses of accurate three-dimensional point cloud data within very less time making it an important alternative for measurement and metrology in industrial applications. The contactless scanning devices provides raw and unorganized point cloud data in the case of intricate free-form shapes like warped surfaces. The contactless scanning systems works on specific principles that includes time-of-flight, triangulation, structured light and photogrammetry (Varady et al., 1997; Schwenke et. al., 2002). Wang et al., (1999) developed a contactless scanning system having 4 axis for data acquisition. Furthermore, several researchers have developed scanning devices based on laser diode and (Charged Couple Device) CCD sensor for data acquisition of the objects surface using laser stripes (Yau et al., 2000; Chang and Chang, 2002). Chang and Chang developed an integrated approach for data capturing by using touch probe as well as laser scanner which are mounted on a CMM.

The non-contact devices are classified as active and passive system by Isgro et al., (2005). Active systems works on using light patterns on any scene to spot its position for measurement. Passive systems, on the other hand, use naturally occurring images produced by reflected light from a natural or artificial source, and they do not use any other type of energy to help the sensors. At the present time, these contactless scanning systems have get hold of good level of confidence for RE applications and laser scanners mainly are engaged for part inspection in industrial applications (Lin et al., 2010; Jorge et al., 2011; Xu et al., 2011; Pathak et al., 2016).

Past literature provides the information about use of coordinate measuring machines (CMMs) for data acquisition, accurate shape, and also quality inspection to conform to the GD&T specifications (Gao et al., 2006; Martinez et al., 2010). Most often, the probe CMMs are used to acquire point data from basic features such as holes, slits, steps, etc., since these features require only a few samples to determine their identification. However, the data collection process with CMM is substantially slow,

since the probe must make contact at each point where a scan is to be performed. In addition, some studies have shown that the planning of CMM data acquisition is a difficult and complex task, as complicated free-form surfaces require higher sample points (Elkott et al., 2002).

With increasing free-form in the industry, whether for aesthetic or functional purposes, data collection becomes an important task for accurate inspection. Since, the parts having free-form shape are costlier and plays an imperative role in final assembly, the complete part data measurement is imperious for effective functionalities (Curles, 1997; Lindau et al., 2013). Moreover, the CMM has ineffectiveness in free-form shape measurement. In addition, the contactless scanners have ability of obtaining millions of point cloud in short duration of time, along with the improved precision in recent times. For all these reasons, the non-contact 3D scanners be used for quality control of industrial components. A general schematic of such a non-contact 3D scanning device is shown in Figure 2.8.

Since, the usages of laser scanners are becoming progressively common in other industrial fields also, it is essential to understand wisely different factors that can be chosen to get the best results. Besides the several improvements in accuracy control of 3D scanners, there are some other factors that influences the overall quality and accuracy of scanned point data (Lee and Chang, 2006; Ali et al., 2006; Mian et al., 2015)

**Figure 2.9** Laser triangulation principle (Curles, 1997), ( $\alpha_s$  is incident scanning angle) (2001)

predicted digitization error considering the effect of scan depth and projected angle on measurement accuracy. The prediction model developed calculates the systematic error having maximum deviation of 25  $\mu\text{m}$ . Shuo and Dar has developed a laser scanning system and suggested in their study that error compensation of the inclination angle data can be used to improve the precision of the system. Mian et al., (2015) performed experimental study and investigated the influence of different scanning factors on the final accuracy of the reverse engineered model. The scanning parameters they considered include laser power, shutter time, measuring field and threshold for reflection. It was found that the laser power and shutter time are inversely related to the final accuracy of model. Threshold for reflection has major influence on the surface accuracy.

Past studies have suggested countless different parameters that are either related to scanning parameters or acquisition instrument whereas current study proposes specific parameters for the same process. Some of the factors that are associated with acquisition device includes scanner resolution (Liang et al., 2016), field of view (Mian et al., 2015) and accuracy (Yin et al., 2014). Ghazali et al., (2011) reveal that scanner resolution significantly affects the accuracy of points captured by comparison of data points captured using 3D scanner with GPS observation. Subsequently, the factors addressed related to scanning factors includes laser power, shutter time and threshold for reflection (Ali et al., 2008). Their study found that the most important factor which affect the quality of point data acquired is laser power. Gestel et al., (2009) proposed a test method for laser scanners based on a planar test artifact. The study also addresses the systematic error evaluation which is based on in-plane, out-of-plane angle and scan depth effect. One similar study was reported, which investigated the influence of range and surface reflectance as the scanning parameters on the data acquisition (Tornincasa and Vezzetti, 2005). In addition, some studies have indicated that the ambient light conditions and the properties of the scanned object are few other factors that are responsible for measurement accuracy. In the research of Lemes and Uzunovic (2009), the influence of ambient lighting on the quality of scanned data has been reported. An empirical relationship was established between the color of the surface of the object, the ambient illumination, and the quality of the laser scan. Similarly, Blanco et al. (2008) in their study evaluates the effect of ambient light on the scanning process. It has been found that

different type of light produce different results which is not uniform. Further, Voisin et al. (2007) in their study shows the influence of illumination (ambient light) on structured light based scanner performance. It was observed that the ambient light more or less affects the range accuracy depending on the original color.

The laser scanning and the touch probe CMM comparative test shows that the ultimate accuracy of the part to be scanned depends on the scanning strategy. The study suggested that single-head alignment is preferable to multi-head alignment during scanning (Martinez et al., 2010). Few specific studies are based on the study of the effects of laser intensity that depends on the roughness of the surface. This study suggests that the intensity of the laser is directly related to the machining process and further an extensive range of intensities for maximum data acquisition were suggested (Cuesta et al., 2009). Further, Kaasalainen et al., (2010) pointed that target object moisture has an effect on the laser scanning performance and its output. In a continuing effort (Kaasalainen et al., 2011), effect of two important parameters such as incidence angle and range on the intensity measurement and radiometric calibration for different Terrestrial laser scanner (TLS) scanners were studied for establishing a correction scheme. In addition, few studies have identified methods for collecting data from transparent and glossy surfaces. They suggested that the provision of coating sprays on the surface would be the solution to such objects. Further, it was clarified from the result that only a variation of the actual surface area of 5-15  $\mu\text{m}$  was obtained is added in actual surface (Mahmuda et al., 2011). Pesci and Teza, (2008) in their study evaluated the influence of surface irregularities (roughness) on the point data provided by laser scanning.

Most of the previous studies consider various factors of the contactless scanning system to obtain a precisely scanned surface. However, attempts to study the influence of scanned surface topology and local geometry have rarely been investigated in the literature (Xi et al., 2001; Shiou and Ali, 2005; Uzunovic and Lemes, 2010; Mian et al., 2015). The effects of relationship among object, image, and the error of the measuring device have been studied (Xi and Shu, 1999). The study shows an absolute error with respect to the nonlinear relationship between the precalibrating factors. This preceding error was also discussed in (Lee et al., 2002), and it was established that distance between laser head and object lead to out-of-plane error.

### **2.13 Discussion on mechanical and physical properties of mold in injection molding**

Additive manufacturing since its inception has come a long way from automobile to biomedical applications. Nowadays, one of the significant applications of additive manufacturing technology is the use in rapid tooling. From the past research, it is now clear those RT tools, as injection molds can be used to produce conventional and practical samples for small or sometimes large-batch production (Pham et al., 1998; Hilton and Jacobs, 2000; Chua et al., 2010). The selection of mold material and their processing have an influence on how it executes during its use throughout its life cycle in injection molding process (Martinez et al., 2011). The different thermal properties of mould materials have significant effect on the mechanical properties of the polymer parts produced in the injection molding.

In 2007, Sadabadi and Ghasemi examined various injection molding process parameters that can affect the mechanical properties in polystyrene composite mold. In another similar study, Yang (2006) studied the influence of different injection molding conditions on the mechanical and tribological behavior of poly carbonate material. In early 2000, Guerrica et al., (2001) performed experiments for determining the effect of melt temperature, injection rate and screw rotation on the mechanical properties of the plastic injection molding parts. In one similar study, Kenig et al., (2001) applied regression analysis and neural network for investigating the effect on the mechanical properties of injection mold parts. In 2000, Bociaga performed a specific study and found that the mold temperature has significant impact on the mechanical and thermal properties of the high density poly ethylene (HDPE) mold. In addition, the effect of injection velocity has also been discussed and reported.

Nagaoka et al., (2005) studied the mechanical behavior of polypropylene material as mold in injection molding. Furthermore, Shi (2008) study investigated the effect on mechanical properties of polypropylene material by optimizing injection molding process parameters using neural network. Tang et al., (2007) found the effect of process parameters on the mechanical properties of two aluminium composites. The experimental trials were performed using Taguchi method and linear relation was found using regression analysis. Ozcelik et al., (2010) observed the influence of melt temperature,

packing pressure on the mechanical properties of ABS polymer material in their study. The mechanical properties include flexural modulus, impact strength and tensile strength. In a similar study performed by Chien et al., (2004) on the examination of mechanical properties and molding behavior of polypropylene parts, it was found that with increase in foaming content from 0.8 to 1.6 % the mechanical properties reduced significantly. Park and Young (2009) studied the effect of mold temperature on different mechanical properties of polyether polymer.

Lee et al. (2007) investigated the compressive strength in layered parts as a function of build direction and determined that the compressive strength is greater for the axial FDM specimens than for the transverse. Panda et al., (2006) in their study performed investigation by measuring the influence of process parameters on different part characteristics that includes surface roughness, dimensional and mechanical strengths. Further, several researchers have studied the effect of processing conditions on the morphological structure that in turn can affect the physical and dimensional characteristics of the mold (Michael and Menges, 1989). Polosky et al. (1998) inspected the impact and tensile strength for polycarbonate and nylon 6, 6 molded in a SL tool and a steel tool. The authors found a 10 % variance in tensile strength between SL and steel tools and the stress levels were usually lesser in the parts from the SL tool due to the sluggish cooling rate permissible relaxation of the parts.

Mohd et al., (2016) in their study determine the tensile strength and dimensional variation of ABS polymer when mixed according to the loading ratio. Their study concluded that high injection pressure and melting temperature will produces less shrinkage. In a similar study, Mehat and Kamaruddin (2010) applied Taguchi and ANOVA analysis to confirm that injection timing is the most significant factor that affects the flexural modulus of the injection molded parts. Seldon (2004) also investigates the effect of molding parameters on mechanical properties on injection mold for different material using experimental design. In a recent study by Farotti and Natalini (2017), process parameters effect in injection molding is considered by determining the change in the mechanical properties of polypropylene polymer. Their study concluded that holding pressure and mold temperature have significant effect on the mechanical properties of mold.

**Table 2.1** Summary of important literature for Mechanical and physical properties of mold

<b>Investigator</b>	<b>Year</b>	<b>Properties</b>	<b>Material</b>
Bociaga	2000	Mechanical and thermal behavior	High density poly ethylene (HDPE)
Nagaoka et al	2005	Mechanical behavior	Polypropylene
Yang	2006	Mechanical and tribological behavior	Polycarbonate
Shi	2008	Mechanical behavior	Polypropylene
Tang et al.	2007	Mechanical behavior	aluminium composites
Ozcelik et al.	2010	flexural modulus, impact strength and tensile strength	ABS polymer
Chien et al.	2004	mechanical properties and molding behavior	Polypropylene
Park and Young	2009	mechanical properties	Polyether polymer
Mohd. Et al.	2016	tensile strength and dimensional variation	ABS
Farotti and Natalini	2017	Mechanical behavior	Polypropylene

#### **2.14 The Knowledge Gap in Earlier Investigations**

This exhaustive literature review, presented above, shows the following knowledge gap that assisted to define the objectives of this research:

1. Though a lot of research work has been done on metallic mold. Due to many drawbacks in metallic mold like heavy weight, high cost, rusting and poor surface finish, difficult machining of metallic mold, application of possibility of employability of rapid tooling mold need to be investigates.
2. Several studies have been reported to improve parts quality in terms of volume shrinkage and warpage and to optimize important parameters of injection molding. In addition, some of the reported literature used nature inspired algorithms such as PSO and its modifications to predict optimal parameters.

3. Earlier the dimensional accuracy of developed component from mold is investigated with vernier caliper or CMM. That makes the inspection process slow and inaccurate, that require adequate skill and expertise. Also, very view literature is available presenting the inspection planning for advance manufacturing process i.e. benchmark part and complex feature parts especially developed by Rapid tooling mold.
4. As far as quality of the part is concerned, most of the work reported is using difficult mathematical approximations, which requires lot of skill and expertise, but only very few of them considered software based conversion. None of them have provided the critical parameters, there factors value and the path for accurate product development.
5. None of literature has proposed for inspection of quality of any benchmark part and complex feature parts developed by rapid tooling mold and evaluation of mold strength, to perform more experiment through rapid tooling mold insert.
6. No work has been proposed yet for the Optimization of warpage and shrinkage of rapid tooling molded thin wall component using modified particle swarm optimization for various injection molding materials.

### **2.15 Research objectives**

The objectives of this research work are outlined as follows:

1. Investigate the possibilities of employing rapid tooling mold inserts in place of metallic mold for injection molding.
2. Development of mathematical model for standard benchmark features to reduce the defects (volumetric shrinkage and warpage) of parts developed by RP mold using Moldflow simulation software.
3. Confirmation and validation of dimensional accuracy of test specimen developed by RP mold using 3D scanner (COMET plus and INSPECT plus software)
4. Optimization of warpage and shrinkage of rapid tooling molded thin wall component using modified particle swarm optimization.
5. Analyses the effects of all the process parameters on the performances of shrinkage and warpage obtained by mathematical models. Find the optimum

value of process parameters, by the analytical model using regression analysis and improve the optimum values by a recently developed modified particle swarm optimization algorithm.

6. Comparison of outcomes (Volumetric shrinkage and warpage) with conventional molds using 3D Scanner and previous literature.

### **2.16 Chapter summary**

The chapter reviews the literature available on different rapid tooling techniques used in production, additive manufacturing (AM) techniques, injection molding process parameter selection, optimization and advances in 3D scanning systems for quality inspection. Furthermore, the discussion on mechanical and physical properties of additive manufacturing mold is also been performed. Based on literature discussed, the research gap in the past research is determined and based on that objectives of the present work are determined.

## CHAPTER- 3

# MATERIALS AND METHODS

The research work presented in this chapter is focused on investigating initial feasibility on determining whether room temperature vulcanizing (RTV) and polymer rapid tool (PRT) can be used as functional injection mold tooling. The main objective of the research was to determine whether the RTV and PRT could mold a set of distinctive features for a specific dimension within the usual tolerance limits and do this repeatedly. Initially, simple geometric shapes were formed and studied, which represent commonly molded features. This was followed by the molding of more complex and commercially available plastic components.

### **3.1 Investigations of Room Temperature Vulcanizing (RTV) soft tooling as functional injection Molding**

Rapid Prototyping is being recognized worldwide by industries for its potential in saving on process time and cost effectively. Rapid Tooling helps rapid prototyping grow beyond its conventional “Feel & Fit” status to “Feel –Fit – Function” status and increasingly becoming popular in product development sector. But it’s potential for short or normal production run is still not realized. One alternative is to use silicon molds for replicating (multiplying) sufficient number of models. As this appends an additional stage in the tooling process it is evident to estimate and predict the dimensional deviation from RP model and its wax replica. This work investigates the dimensional accuracy of the wax replicas generated out of component molded on rapid prototyping machine. Further, to study the influence of process a 3 factor 4 level (L16) orthogonal array experiment is designed as per Taguchi method and result is reported.

### **3.2 Experimental set up**

The fused deposition modeling based native R3D2 ELAM machine was used for modeling the pattern (Shrinkage Stepped bar). The build material used was ABS wires of

1.7mm diameter size. RTV molds were planned and made with Mold Max 60 Part A & Part B supplied by *smooth-on* products distributors Mumbai. A wax injector 2.5 Kg was used for injecting the wax into the silicon rubber molds. The respective wax replicas dimensions were recorded for calculating dimensional deviations and ANOVA.

### 3.2.1 Selection of Test pattern (Model)

In view to win the acceptance of precision casting industries, it was decided to use the most popular test pattern used by the industry, hence stepped shrink test bar was selected. The important dimensions to be observed in X, Y and Z directions and a cylindrical hole were included for dimensional deviation study, as in the figure 3.1. It is a good choice for its shape, size, manufacturability etc.

**Figure 3.1** Stepped bar pattern developed for additive manufacturing

### 3.2.2 Entry Level Additive Manufacturing (ELAM) for generation of RP pattern-

The use of affordable AM machines is now locating its place in education where students can feel, fit and sense the fabricated objects. One of such low-cost ELAM machines was used as shown in Figure 3.2. One of the advantages of ELAM systems is that they can use open source slicing software such as Slic3r, Cura, kisslicer. Another advantage is that these machines come with a single nozzle and the support material can be extruded through the same nozzle in a sparse manner. This cuts the cost of machine as wide choice of feedstock filaments are possible. It comprises a horizontally translating (x-y) heated bed platform with a functional build area of 200 mm x 220 mm and vertical translating

(z-direction) extruder attached with a nozzle. The maximum build height of the machine is 200 mm. The extrusion process is governed by a stepper motor with a feed of 1.7 mm diameter ABS filament into a heated 0.15 mm diameter nozzle. The R3D2 ELAM machine used to construct parts with a layer thickness of 0.075 mm. The process of printing the parts on R3D2 ELAM system begins with the CAD model saved in STL format. The surface defining the design must not contain any discontinuity (non-manifold edge). The part could be re-oriented and repaired for optimum print quality using Netfabb and MeshMixer. Slic3r software was used to slice the part with suitable layer thickness and for adjusting other print parameters before G-code generated. Initially, the extruder head and printer bed were heated to a predefined temp and then extruder head begins to extrude molten plastic to build prototype taking shape from bottom to top layer by layer. Acetone-ABS mixture is used on printer bed for effective part adherence. Acetone solution offers a satisfactory adhesion of the part on printer bed during the printing process.

**Figure 3.2** Schematic of R3D2 entry-level AM Printer

### **3.2.3 Selection of RTV Silicon compound**

Mold Max 60 RTV compounds were selected for its relatively high shore hardness (60), low linear shrinkage .0015 in/in, high mixed viscosity (20,000cps), thermal conduc-

tivity ( 0.347W/mK), pot life (40min),Cure time(24hrs) etc. The constituents for RTV were shown below in Table 3.1.

**Table 3.1** Constituent of RTV mold and Si rubber for soft tooling

Mold star series	Mold star 15 slow
Platinum Si rubber	Platinum Si rubber
Polyorganosiloxanes	Polyorganosiloxanes (Mixed)
Amorphous silic	Petroleum Distilate
Platinum Silixane	Mineral filler
Mineral filler	-
Si rubber compound	Polyosiloxanes
Triglyceride sand rubber	Carlinoria Proposition
Butganotin	-

**Figure 3.3** Si rubbers for RTV soft tooling

**3.3 Methodology to prepare RTV silicon rubber mold –**

Mix required amount of liquid rubber compound into mixing container (1A:1B) by volume thoroughly. Pour over prepared model (RP pattern) and let it cure to a solid up to 24 hrs. After solidification the bottom part will be prepared known as Drag. Similarly make top part of mold known as Cope.

**3.3.1 RTV Mould preparation**-The mould box consist of cope and drag as in the Figure 3.4 (b). Required weight of the compound A and B are mixed in a jar and bottom mould was made. After 24 hrs of curing time top mould was also made. Mould alignment and guide pins are very important and were taken care. The pattern was removed and mould was ready for filling. It is recommended to use a suitable release agent to perform a compatibility test between the rubber compound and the plastic RP pattern. Just observe whether the rubber becomes gummy when smearing on a small uncritical area of the pattern. Use protective wear (nasal mask, sleeves, gloves, goggles). Care! If the mixture is spilled, the work area to be damaged.

**Figure 3.4 (a)** RTV silicon rubber mold

**Figure 3.4 (b)** Mold and Patterns

**3.4 Pattern by Wax injection** - It was decided to use a wax injector of 2.5 Kg, with temperature (range 30-150°C PID controller) and pressure (range 0- 2Kg/cm<sup>2</sup>) control provisions. Refer Figure 3.5 adequate number of runs were performed before getting the injector stabilized. Further trial runs were also tried to understand the process parameters suitable for the proposed test bar. Then the factors and levels were decided to perform design of experiments. Sixteen combinations were tried and wax replicas were identified as 1 to 16.

**Figure 3.5** vacuum wax injection machines

**3.5 Process parameters for the production of wax patterns**

To identify the process parameters that affect the quality of the investment cast parts, an Ishikawa Cause and Effect diagram was created as shown in Figure 3.6. The dimensional stability of the wax pattern produced by the IC process may be affected by the following process parameters, as presented in the Ishikawa Cause Effect Chart.

**Figure 3.6** Ishikawa cause effect chart for wax pattern

**Variables for Wax mixture** – composition includes different waxes and additives, viscosity, thermal conductivity.

**Variables for Wax injection** – injection temperature, injection pressure, injection time.

**Mould Variables for inside cooling** – cooling time, ambient temperature of the mould.

**Air cool based variables** – ambient temperature, ratio of air flow.

**Variables for mould** – mould material, durability, sufficient venting.

**Individuals based variables** – fatigue, idleness, awareness

The process parameters, injection temperature, injection pressure and injection time were considered to demonstrate their influence on the dimensional stability of the wax pattern made by the IC process. Additional parameters such as wax composition, ambient temperature, and vacuum pressure, the pattern cooling inside the mold and after ejection from the mold were stable throughout the analysis. The range of selected process parameters were determined by performing the experiments with one variable at a time approach. Table 3.2 shows the process parameters, their design symbols and ranges. Based on preliminary experiments performed in the laboratory, the injection temperature range of 75 to 90°C was selected. The results showed that the fluidity of wax was not proper at temperatures below 75°C, the wax mixture used in the experiment resulted in incomplete filling of the mold cavity, and wax injection at temperatures above 90°C resulted in more wax mold shrinkage. The injection pressure was chosen in the range of 0.8 to 1.1 kg/cm<sup>2</sup>. The wax shrinkage was observed to be minimal within this range. The range of injection time between 4 -10 seconds was chosen for the reason that the cavity was not completely filled when the injection time was less than 4 seconds, and that when the injection time exceeded 10 seconds, liquid overflow was caused to wax out from the mold. In this study the response parameter was linear shrinkage (LS), expressed in percentage, which is calculated by finding the difference between the pattern size and dimensions of the mold.

### **3.6 Experiment & observation**

A four level three factor DoE was planned for Table 3.2 and Taguchi L16 orthogonal array experimentation procedures were performed to generate the respective responses.

Dimensions of the RP replicas (Wax patterns) were measured and compared with respective CAD dimensions and RP contraction was calculated as shown in the Table 3.3.

**Table 3.2** L16 experiment Factors and Levels

S. No.	Factors	Levels			
		1	2	3	4
A	Temperature ( <sup>0</sup> C). T	75	80	85	90
B	Pressure (Kg/cm <sup>2</sup> ). P	0.8	0.9	1.0	1.1
C	Time (min).t	4	6	8	10

**3.7 The responses** - The linear dimensional deviation in X, Y, Z and Hole diameter were calculated taking the respective RP dimensions as references. And percentage deviations were calculated as given in the Table 3.3. In most of the cases it was shrinkage hardly expansion was noticed. The S/N ratios were calculated, trend graphs were plotted for Temperature, Pressure & time. The responses were used for calculating the ANOVA using MINITAB16.

$$\frac{S}{N} = -10 \log \left[ \frac{1}{n} \sum_{i=1}^n y_i^2 \right] \text{ ——— (3.1)}$$

**Table 3.3** L16 Responses of Experimental work

### 3.8 Results & discussion

For the sake of simplicity the dimensional deviation of RP replica with reference to RP pattern is termed as shrinkage. Then percentage shrinkage are estimated in X, Y, Z directions. The selected test bar for the study in this paper is the one being regularly used in the precision casting sector. This might enhance the adaptability and acceptance from the end users and hence linking the findings with the industry might become easy. Since FDM models( patterns) have contraction in X,Y ,Z directions it was advised to quantify the contraction compensation of wax ( RP replicas) also in X,Y ,Z directions. This might help when we decide for providing total (cumulative) compensation on CAD drawing stage. It may be avoid estimate individual.

It can be read out from the experiment that the shrinkage in

Y Direction is 3.5 to 6 %

Z Direction is 3.5 to 4.5%

X Direction is 2.5 to 3.5 %

Shrinkage on one typical internal dimension (Hole diameter) is an example for restricted dimensions, and it is clear that when the wax is restricted by the mould it hardly shrinks. The shrink value observed is +0.50 to – 1.7%. One can well assume the average value as approximately – 1.0%. ie it has an apparent expansion on the restricted dimensions; this is a complex phenomenon, it may even explore the thermal expansion of the RTV, accuracy of RP on cylindrical dimensions etc. to explain it. Above values reported represents ‘RP to Replica contraction’ and the ‘alloy contraction ‘always is available with the shop floor for different alloys cast. But the RP contraction is quite a controversial in spite of

several technical publications. However academia agrees with RP model's behavior that it shrink in X, Y & Z directions differently and it tends to expand in its z direction. The typical values we got to represent RP contraction is 0.34 to -3.0%, -0.2% and 0.13% respectively on Y, Z and X direction. Once we put together all the three contraction components we can quantify the compensation require on the CAD. It's worth to recall now that wax contraction is hardly 1% in metallic mould, it shows wax behaves differently in metal moulds and in RTV moulds. This may be due to the difference in the respective thermal conductivity (Thermal diffusivity) and modulus.

In the precision castings sector the above findings are unacceptable and remain irrelevant as it is quoted without reference and limits. It's very important to notice that in X direction which is taken along the direction of wax flow /wax injection the wax replica has a tendency to shrink less compared to Z direction which is taken to be perpendicular to the wax flow. This conform to the technical literature published by RTV suppliers that its shrinks less in the flow direction [[www.xiameter.com](http://www.xiameter.com)]. The applicability of above shrinkage values is 0 – 150mm, 0- 40mm and 0-25 mm for X, Z and Y axes respectively. The Taguchi experiment S/N ratio and trend charts gives us the impact of Wax temperature(T), Hold time (t) and Wax injection pressure (p) on the output we measured in the form of shrinkage. It's may be inappropriate to term the response as shrinkage ; it is shear 'dimensional deviation' since it is not attributed to just a phase change ,in fact there appears an interplay of thermo physical properties of RTV compound and process factors involved in mould making, like thermal diffusivity, thermal conductivity, mould wall thickness, Modulus ( strength) ,wax flow direction, size & geometry besides the process factors we considered. It can state from the trend graph that 80 – 90 °C wax temperature, Pressure at 1 bar and hold time 8 minutes give best result in Y direction where in Z direction pressure is not very impactful –Temperature and Hold time is more impactful and it is more evident as values are increased. The Injection temperature is more impactful in all the cases.

**Figure 3.7** Effect of process parameters on linear shrinkage and S/N ratio

It is observed that impact of pressure is very different in Z & X directions, in Z direction it is found more impactful, may be, the hydrodynamic pressure is more on across the flow, i.e perpendicular to X (injection) direction.

The response table of the S/N ratio gives the optimum value against each factor of the process. This is based on highest value criteria. As such 90<sup>0</sup>C (D1) for Temperature, 0.9 Kg/cm<sup>2</sup> (B3) for Pressure and 8 minutes (C2) for Time constitute the best combination of set of values ensues the optimum and minimum shrinkage on the wax replica, with factor Temperature and Pressure respectively as the most influential and the least influential in the experiment. And it is observed 2.0 to 2.5 %, 3.0 to 3.5% and around 5% shrinkage on X, Y and Z dimensions after optimization of shrinkage on wax replicas.

This work reports shrinkage behavior of wax in the RTV silicon rubber compounds under the influence of wax injection temperature, Mold hold time and Wax injection pressure and help open up the black box of ‘cumulative shrinkage compensation’ required on the CAD drawing when integration of RP with precision castings is attempted. This is the need of the present day precision casters but unfortunately it is a complex issue and a live challenge to the academic community and researchers. Though the wax pattern generated by RTV demonstrates its capability to be an alternative to metallic moulds its full potential can be realized only when RTV & RP go hand in hand. Though sporadic commercialization of RTV & RP integration is being reported a comprehen-

sive optimization and standardization is essential before we could win the trust of precision cast house.

**Table 3.4** Response Table for S/N Ratio

	Factors	A	B	C	D	Delta	Rank
1	Temp	-22.82	-22.48	-22.53	<b>-22.30</b>	0.52	1
2	Time	-22.83	-22.49	<b>-22.38</b>	-22.48	0.45	2
3	Pressure	-22.60	<b>-22.49</b>	-22.51	-22.58	0.12	3

The data in optimizing the shrinkage on the wax replica using process parameters Temperature, Time and Pressure with Taguchi L16 orthogonal array experiment are shown in table 3.3. This study optimizes the factors for minimum shrinkage. S/N ratio is calculated as the equation (3.1) with lower the better criteria. Where  $Y_i$  is the value of the quality features for the  $i^{\text{th}}$  attempts,  $n$  is the number of iterations.

**3.9 Investigation of FDM modeled Polymer Rapid Tooling (PRT) for Plastic Injection Molding** - As stated in previous section, in order for the RTV mold to be feasible for use, it must be able to mold the product that meets to the specified geometry and do this repeatedly and within the tolerance range limits. This means that the mold must be stable and robust. For the purposes of this study, the stability of the mold refers to a form that corresponds to specified dimensions for several cycles, which results in acceptable components. Robustness refers the resistance of mold to degradation and, consequently, limiting the change in size from part to part. To investigate the robustness and stability of PRT shapes, parts were selected and molded using both PRTs and conventional metallic tools. Each molded part contained several important functions. After molding, the pre-selected characteristics were measured in comparison with the calculated dimensions and evaluated with high accuracy. Then, the measurement data were tracked from shot to shot to determine behavior and robustness produced parts.

The measurement data from the molded parts will then be analyzed to determine:

- If the part reaches the required size (within the specified tolerance)

- If the component meets the size of most components generate

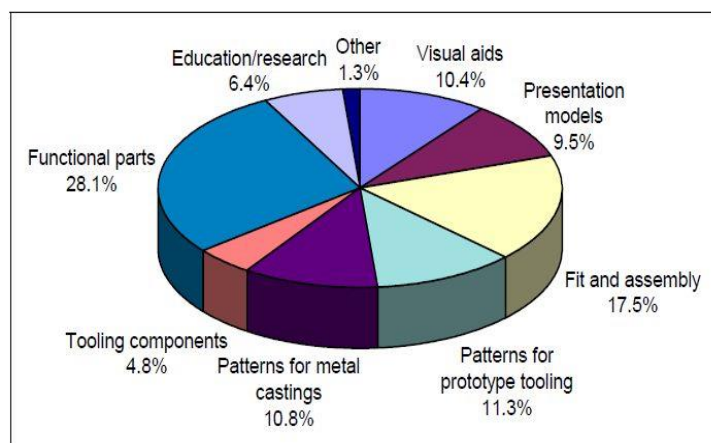

- the rate at which the parts changed in dimension depending on the number of shot cycles that the shape experienced. Although length and Width are not necessarily geometric features, it is a simple way to compare a molded component regardless of overall complexity. To a lesser extent, diameters were also examined to depict non-linear features such as cylinders, pads, fillets and curves.

With the advances in materials along with the new access and low cost plastic based AM equipment, direct use Polymer Rapid Tools (PRTs) would be a far more advantageous option in creating injection molds for low and highly flexible production. However, the use of polymer based direct rapid tooling by industries is curtailed due to the issues with the dimensional stability of the polymer based rapid tooling molds. Apart from dimensional tolerances, there are also issues with the life of these polymer based mold as they wear fast and are also not able to sustain high injection pressures in an Injection molding machine. Another, major problem with the polymer based rapid tooling is the poor thermal conductivity of polymeric materials due to which there is an increase in the cooling time and ultimately leading to decrease in productivity. Therefore, before proposing polymer based rapid tooling as a solution to industries to reduce the product development time and bring down the costs, a thorough study of the issues related to the same is imperative. This primary objective of this work is to investigate the dimensional accuracy of striker (RP) component produced by ABS mold inserts. For dimensional accuracy a reverse engineering technique 3D scanning is used which is compared with CAD file and inspected with COMET plus software. Further, the outputs are validated with vernier caliper. The mold insert is manufactured by Fused Deposition Modeling (FDM) technology which is used on injection molding machine.

With short production cycles, excellent surfaces of the products, tight tolerance complete automation capability and facile molding of complex part geometry, Injection molding (IM) is crowned as the most popular molding process for manufacturing thermoplastic parts. However IM requires complex and costly tooling and it is almost uneco-

nomical to plan a short production run. Hence IM personals are confronted when a one-off production or trial run for product development are warranted. The proliferation of rapid Prototyping (RP) tends to rope in IM tool design and development simplified. RP in late eighties began with rapid generation of prototypes for feel and fit purposes. Today, Rapid prototyping (RP) has emerged as a third industrial revolution reengineering the entire manufacturing transforming the way in which products and systems are designed and manufactured as a fascinating area of study called rapid manufacturing (RM) covering >50% of the additive manufacturing (AM) output (see Figure 3.8). This is affected through emergence of a new field of science called Rapid Tooling (RT). RT is being expanded as Soft Tooling, Hard Tooling, Direct Tooling, and Indirect Tooling and is the link between RP and RM.

Today, RP technology is slowly being recognized as a class of commercially viable production techniques characterized by significantly low tooling cost and lead time. The revenues from end-product manufacturing accounts for 34.7% of the total additive manufacturing (AM) market, which, according to Wohler's report, reaches \$ 1 billion (see Figure 3.9). AM has a host of technologies (FDM/SLA/SLS/3D printing/poly jet) employing different types of feed materials like solids(filaments), liquids( resins), powders but majority employ polymer based feed stock hence the thermal resistance and fatigue strength are always a concern when it was employed to endure extreme conditions of stress and temperature entailed in tooling. However as per the sporadic information available in the literature; the development of

Source: Wohlers Report 2013

**Figure 3.8** Applications of additive manufacturing

SLA based IM tooling was seen attempted however no commercialization has yet been reported. Metal based AMs are the best but are unaffordable. FDM with its conventional ABS and poor part density it is being ruled out for IM tooling project. One promising option is FDM based Polyjet technology which employs digital ABS, rubber like elastopolymers etc. This work investigates the development of IM tooling through Polyjet technology.

**Figure 3.9** Revenues from the production of parts

**3.10 Methodology to develop PRT mold** - Polyjet technology is a variant of FDM technology licensed to Stratasys. These machines manifest extreme level of surface finish ( $R_a 3$ ) and part definition with improved density, physical properties etc. Before manufacturing of mold inserts of part component on 3D Polyjet it is created on Autodesk inventor 3D modeling software according to their dimension as shown in Figure 3.10.

**Figure3.10** Designed geometry with dimension of striker mold

### 3.11 Material selection and properties-

The digital acrylonitrile butadiene styrene (ABS), available from Stratasys Inc was used as a matrix polymer. This ABS is an FDM grade polymer used by Stratasys for the production of recommended prototypes on the FDM machine. The specific gravity of ABS was 1.05 g / ml. Acrylonitrile-butadiene-styrene is an amorphous thermoplastic consisting of three monomers, usually containing 15-35% of acrylonitrile, 5-30% of butadiene and 40-60% of styrene (see figure 3.11). The Properties of ABS means, Acrylonitrile: chemical resistance, heat resistance and high strength, Butadiene: toughness, impact strength and low-temperature property preservation, Styrene: rigidity, surface appearance (gloss) and process ability. Its properties may vary according to the volume fractions of the monomers used in the mixture. While acrylonitrile is responsible for the bonding of contiguous chains and the resulting strength of the ABS terpolymer, styrene imparts a shiny and impermeable appearance to it. The rubbery butadiene provides the ductility and impact resistance of the ABS (Designing Site Retrieved May 2010). The FDM-ABS is an environment-stable thermoplastic without significant distortion, shrinkage or moisture absorption. It is 40% stronger than standard ABS over impact and flexural strength. Its more robust layer makes the perfect material to create long-term parts for form, fit and functional applications. Due of these advantages, Digital ABS was preferred as a matrix in the development of the new metal-polymer composite.

**Figure 3.11** Monomers used in thermoplastic ABS

**3.12 Working principle of Polyjet Direct 3D printing** - Poly-Jet Modeling is an additive manufacturing technique with a selectively ink jetting of UV-curable photopolymer resin as shown in Figure 3.12. First, the photopolymer is jetted onto the buildup platform by the printing head. Simultaneously the photopolymer drops are leveled by a roller and solidified by a UV- light. Subsequently the platform is lowered. Like this, a part is generated layer by layer. The replication and enhancement of the photopolymer material layers is a solid three-dimensional model than it is not perfect. In order to prevent collapse of structures during production, gel-like support in the material is designed specifically for intricate geometry with the model materials. After the model is completed, the substrate can be easily removed by hand and sprayed with water to leave only the cured photopolymer material.

**Figure 3.12** Polyjet 3D printers for printing mold, Barnatt C. (2013)

**Table 3.5** Parameters of Polyjet 3D printer Component/mold

Type	Stratasys Objet350 Connex
Material	Digital ABS
Bed temperature	35°C
Chamber temperature	35°C
Layer Thickness	0.032 mm

Digital ABS is suitable for simulation of parts requiring high impact resistance and shock absorption of 65-80 J / m and a deviation of heat temperature at 58-68 ° C (136-154 ° F). It is a high temperature material synthesis of unprecedented dimensional stability of heat resistance. The material can simulate the thermal performance of engineering plastics and is ideal for testing applications such as hot polymer flow in mold insert cavity.

**Figure 3.13** 3D printed core and cavity

### 3.13 Hand Injection Moulding machine to develop the part

Thermoplastic or thermoset material is heated to be plasticized in a cylinder at a controlled temperature and then forced under pressure through a nozzle into a gate, runner, sprues and cavities of the mold. The solidification of resin undergoes rapidly. After solidification of molten material mould is opened and the part gets eject. Injection moulding is propagates in the production of glass-reinforced parts.

The mold forms, shapes and cools the plastic material into the required product shape. The temperature setting for the PP injection is based on the MP of the PP (164°C) it was advisable to set a temperature 180°C to start with the experiment. The PP beads were heated in the barrel to test the melting and oozing out of the liquid plastic threads the nozzle by manually pressuring through the plunger. The molding was uniformed hence the temperature was gradually increased in steps from 190, 200 and 210° C.

**Figure 3.14** Hand Injection Molding (HIM) Machine for trial

It was observed that the mold was getting damaged at the injection point due to applied pressure (at the plunger runner contact area). Always it needs to avoid the direct machine nozzle contact to printed tool. Here a metals (MS) plate is used to resolve the problem by minimizing temperature and pressure intensity at the injection point and converted point load to uniformly distributed load.

**Figure 3.15** Damaged mold at the injection point

**Figure 3.16** Metals (MS) plate for minimizing temperature and pressure intensity at the injection point

**Figure 3.17** Progressive stages of the component made in the trial runs

During the run time whenever the mold got over heated the component got sticky and gummy and did not form well. It needs to be probed. Designing of proper Cooling channels may be a solution. The next figure shows the damage and non-formation of the part due to high temperature 200°C and above. The part non-formation during the run was not possible to run the mold continuously. It was found the temperature 190°C was good to get excellent mouldings. The product coming from the nozzle temperature controlling from 170 to 190 °C is acceptable.

**Figure 3.18 (a)** Part sticks to the mold cavity

**Figure 3.18 (b)** Quality parts (striker) productions

It was found at temperature above 200° C the part formed were rejected. This was applicable even at low temperature injection after a brief run of 5 shots. This was due to mold getting over heated due to dull dissipation of heat from the mould cavity.

**3.14. Reverse engineering to check the accuracy of RP-** A three-dimensional scanner is used to capture the physical object's features through lasers, lights, or X-rays and generates dense dot or polygonal meshes. Before scanning a striker mold part is placed on the table. The physical object can be digitized using 3D scanning technologies such as Coordinate Measuring Machine (CMM) or non-contact 3D scanning technologies such as laser scanners, structured light digitizers, and so on. The point cloud of a manufactured part will be aligned to a CAD model and compared to check for differences after inspection. The part production procedure was established in the HIM machine and the readings on dimensional accuracy of the part are shown in Figure 3.19

Figure 3.19 3D scanner for inspection of part component

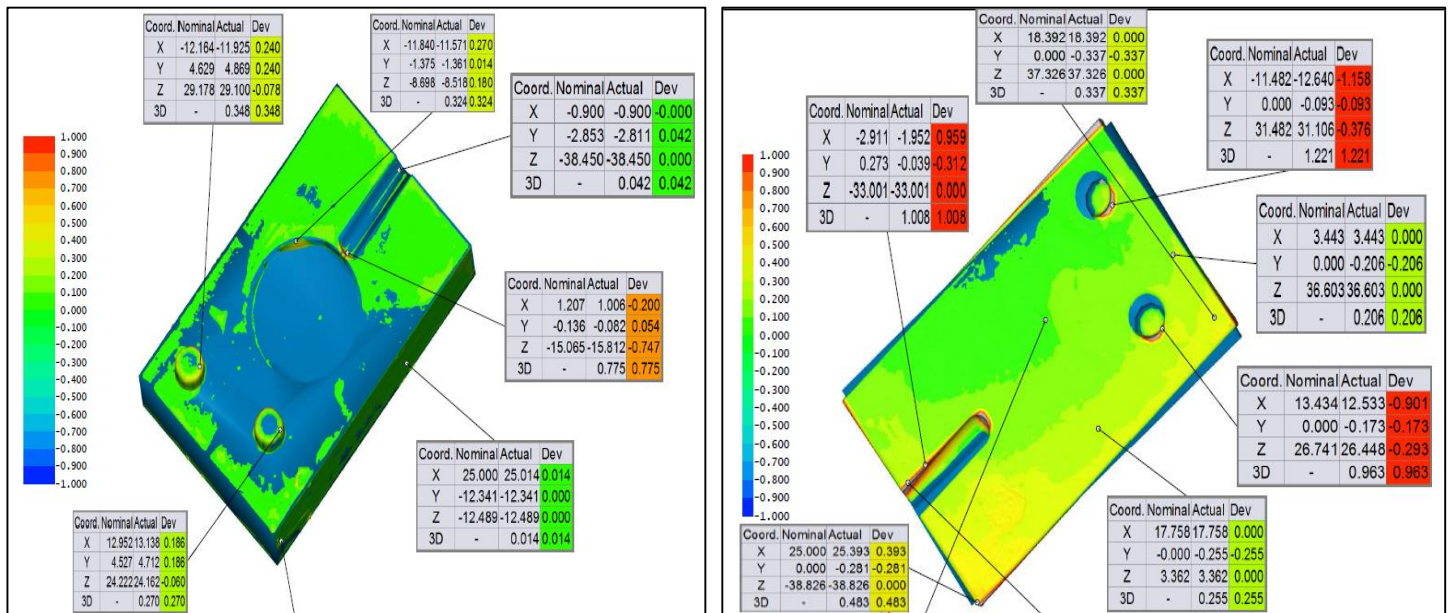

Figure 3.20 Inspection of specimen with 3D scanner

**Figure 3.21** Inspection results of component

**Table 3.6** Dimension of measured part using 3D scanner

Dimensions (mm)	Nominal	Mold	Part

<b>Thickness</b>	3	2.920	2.98

The Digital Caliper is a precision tool that makes it extremely accurate to measure inside and outside distances (see Figure 3.22). The instrument shown below is a digital caliper as the distances/measurements, are read out from a LCD display. The display is operated with the on/off button. The external jaws should then be brought together until they touch each other and the zero buttons need to be pressed. The digital caliper can then be used to measure distances. Always go through this practice while turning on the display for the first time.

**Figure 3.22** Digital Vernier Caliper for measurement

The material to be measured is located between the outer jaws and carefully brought together. Tighten the locking screw so that the jaw does not move apart. The digital display is then able to read. The measured distance can be note down by in metric and imperial values by operating the inch/mm button. Table 3.7 shows the dimensional results using vernier caliper for comparison with reverse engineering results. As clearly seen the results are in accordance with reverse engineering results.

**Table 3.7** Dimensional results using Vernier Caliper

SI. No.	Thickness (mm)	Diameter (mm)
1.	2.9	29.31
2.	2.98	29.54
3.	2.95	29.36
4.	2.95	29.41
5.	2.93	29.29
6.	2.89	28.9
7.	2.89	29.32
8.	2.96	29.15
9.	3.02	29.26
10.	2.96	29.20
<b>Average</b>	2.943	29.274

The injection molding is an intensive mass production process hardly amenable to product developmental short run trials. In the fast changing product style and customer taste

the plastic industries are felt the paradox of prototyping and mass production increasing-ly. Hence it's a global need to introduce new Time Compression Technologies (CTC) to manufacturer prototyping molds economically. Polyjet based additive manufacturing (AM) is potential and promising CTC technology to prototype injection molds for typical short runs. Polyjet CTC is going to be a viable answer to the long standing prototyping issues in the polymer injection molding industries. As compared with measure dimension through vernier caliper the scanned part of striker cavity is almost similar.

### **3.15 Chapter Summary**

The key motive for this study was to investigate feasibility by determining whether PRT/RTV shapes can meet the desired physical dimensions within tolerance limits across a range of geometries and complexities. In particular, it was investigated whether the dimensional stability observed on a simple feature object can be consistently maintained in components with a higher degree of geometric complexity. At the same time, the dimensional stability of PRT/RTV molds was evaluated by cycling the molds until failure and tracking changes and deviations over time.

In addition, the degradation of the PRT form was investigated use of convention-ally produced metal molds as a basis for comparison. In addition, information was col-lected during the course of the experiments to support future research and feasibility.

## CHAPTER- 4

# MECHANICAL AND PHYSICAL CHARACTERIZATION OF DIGITAL ABS

This chapter introduces the digital ABS polymer for mould material, manufactured by means of Polyjet technology and was examined as an alternative for rapid tooling. Based on the manufacturer description, digital ABS is a resin particularly developed to protect against high temperatures and pressure. The key purpose of the present study is to examine a new material for the mold fabrication during the injection process. In this study, the analysis is carried out on digital ABS for the dimensional and surface stability and also studies the final casting properties. For the aforementioned analysis, mechanical properties of the samples were considered and further bending, tensile and impact tests were performed by measuring their hardness. For measuring the PET crystallation differential scanner calculators (DSC) are used.

**4.1 Sample geometry and used materials-** The geometry of the part considered in the present study is shown in Figure 4.1. It is in accordance with the ASTM D638 standard for polymeric part and testing for the ASTM D790 standard tensile test. The bending as well as the impact strength analysis was performed on the similar samples, since based on ASTM standard the sample dimension should be between a thickness range of 3.0-12.7 mm and width must be of 12.7 mm. The same tensile specimen was used for hardness test also.

**Figure 4.1 (a)** Tensile test sample

**Figure 4.1 (b)** Bending test specimen

The moulding material CP 204 PET was considered as it is extensively used in industry and is not difficult to mould. To make a heterophasic (stereoblock) copolymer (Braskem, 2012) it is copolymerized with ethylene-propylene rubber (EPR).

#### 4.2 Mould inserts materials

The digital ABS polymer is a mixture of two materials having RGD515 and RGD535 that encompasses acrylic and metacracheal monuments, urine oligomes, isoborine, epoxy and other acrylic (Stratasys, 2011a; Stratasys, 2011b). Based on manufacturer specification, when removed from the 3D printer, it has a shock resistance of 55-70 J / m and a heat transfer temperature (HDT) of 48-58 °C. The digital ABS mold can be manufactured through a polyjet machine that can mix the polymers RGD535 and RGD515 in a predefined ratio. The SAE 1045 steel insert was considered for comparing the effect of mold insert on the final properties of mold, extensively used in injection molding. The main properties of these two materials are shown in Table 4.1.

**Table 4.1** Properties of SAE 1045 and Digital ABS materials

<b>Properties</b>	<b>SAE 1045</b>	<b>Digital ABS</b>
Thermal conductivity [W/m.K]	52.7	0.17-0.19
Density [g/cm <sup>3</sup> ]	7.65	-
Specific heat [J/kg.K]	790	-
Coefficient of thermal expansion [K <sup>-1</sup> ]	12.3	-
Modulus of elasticity [GPa]	190	2.5-3.0
Tensile strength [MPa]	410	55-60

### 4.3 Design and manufacturing of mould

The two different samples used in the present research are joined in a pair of mold inserts as shown in figure 4.2 (a). The arithmetical simulation was performed on Moldflow interface to check runner balancing and filling in the injection process [see figure 4.2(b)].

**Figure 4.2** (a) 3D model of mold inserts; (b) Numerical simulation using Moldflow. The runner channel is semicircular (radius 3 mm) and the profile of the gate is fan shape. Since the shape of the cavity is extremely simple and easy removal is possible by hand, the need of an ejector system not required for the mold. Furthermore, a cooling system arrangement was also installed for the used metal inserts (Figure 4.3).

**Figure 4.3** Metal inserts with cooling channels

A CNC machine is used to machine the SAE 1045 insert, and the digital ABS insert (see Figure 4.4) was printed on the Stratasys Connex 500 by means of a shiny selection with the cavity shape on top. As Zonder and Sella (2013) suggested, the direction of printing selected in such a way that the polymer flow direction is aligned with the printed line. The digital ABS insert has not been surface finished, in order to analyze the surface of the insert during the plastic injection process. It was necessary to adjust the insert just by slightly adjusting the sandpaper so that the metal mold plate can be attached to the insert and the metal sprue bush can be assembled. In order to execute the injection, all metal inserts are assembled into metal injection molded specially planned for the aforementioned purpose.

**Figure 4.4** Digital ABS mold inserts

#### **4.4 Process parameter and material selection for injection molding experiments**

An Advanced injection molding machine Arburg 370S 700-290 is used and based on previous experience and past studies, the process parameters are defined in the cavity shape and mold used here (Volpato et al., 2011). Table 4.2 exhibit the parameters that are mainly involved in injection of metal inserts. These values are used as a preliminary point for defining the process parameters of the digital ABS material. As shown in Table 4.2, there

are 5 shots are needed to do this. This is usually a commonly employed method with use of polymer inserts in the injection molding (Salmoria et al.2008; Baretta et al., 2007).

**Figure 4.5** Digital ABS Insert with tensile cavity

**Table 4.2** Injection molding parameters for inserts

<b>Parameters</b>	<b>SAE 1045</b>	<b>Digital ABS</b>
Injection time (s)	12	20
Injection temperature (°C)	210	195
Injection pressure (MPa)	35	18
Injection speed (mm/s)	15	10
Holding pressure (MPa)	24	21
Clamping pressure (MPa)	100	32
Holding time (s)	12	32
Mould temperature (°C)	35	30
Cooling time (s)	8	40

The different parameters used were determined by considering the lowest strength of the chosen material. Usually, it is general exercise to apply polymer resin inserts for injection molding (Salmoria et al., 2008; Baretta et al., 2007). The temperature senses for digital ABS inserts were measured with a contactless digital infrared temperature gun thermometer having resolution of 1°C at varying locations on the insertion surface. Supercritical CO<sub>2</sub> was used as a cooling fluid. An experiment was performed to test the effect of spraying a cooling fluid on the digital ABS tool to rapidly cool it between shots. The next shot was taken immediately after spraying the cooling fluid onto the digital ABS mold. After the supercritical CO<sub>2</sub> sprayed on the tool, it was measured that the mold temperate is dropped to 9 ° C as shown in the figure 4.6.

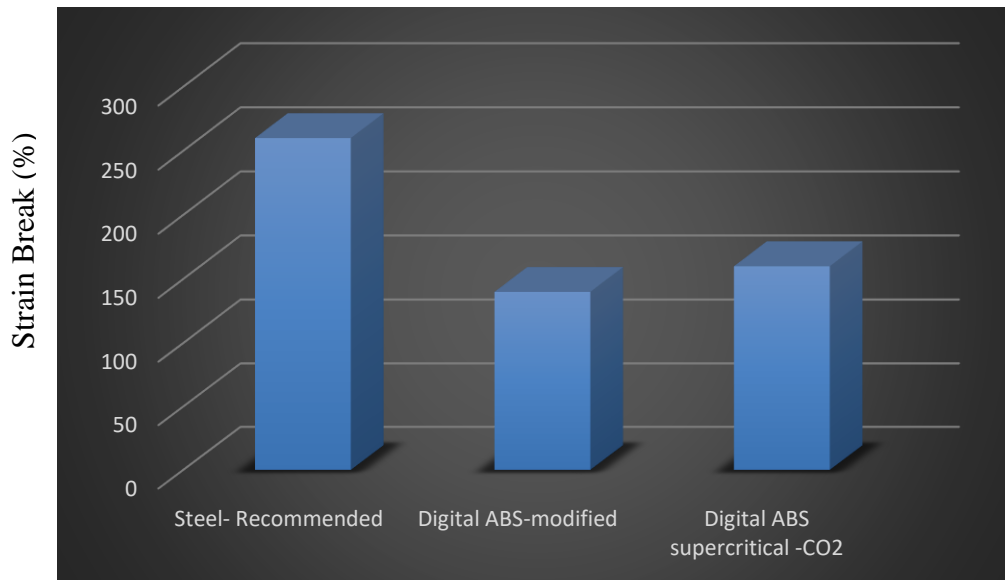

**Figure 4.6** Temperature of Digital ABS Insert after supercritical CO<sub>2</sub> is sprayed

The injection temperature was set at 25° C for the insert materials. Therefore, the next cycle of injection begins only when this temperature was reached. After setup, giving of total 50 shorts, 45 samples were made with digital ABS. The metal inserts temperature was controlled by incorporating a cooling system and maintained at 25°C prior to the start of the new cycle.

**Table 4.3** Molding parameters to conduct the experiments

<b>Properties</b>	<b>Steel Tool- Recommended</b>	<b>Digital ABS Tool- Modified Conditions</b>
Mold Open Time (s)	9	240
Melt Temperature (°C)	210	182
Injection Time (s)	1	4
Packing Pressure (psi)	170	175
Packing Time (s)	20	30
Cooling Time (s)	30	30
Molding Material	PET	PET

**Figure 4.7** Plastic tool strain at break varying melt temp, injection speed and supercritical CO<sub>2</sub>

The fracture strain from molding using polypropylene in a plastic mold with an initial mold temperature of supercritical CO<sub>2</sub> of around 9°C is shown in Figure 4.7.

**4.5 Dimensional and Surface analysis-** The main dimensions for performing the dimensional investigation of the cavity and samples made using digital ABS inserts is illustrated in Figure 4.1 (length, width and thickness). The sample was measured and reading are recorded with a vernier caliper having a least count of 0.01 mm. A Coordinate Measuring Machine (CMM) (Zeiss, UM550) was employed to recognize deformation within the cavity insert. Furthermore, a 3D profilometer is employed to analyze the surface of the digital ABS inserts. Figure 4.4 shows that the measurements were performed inside the tensile cavity, near the gate. All the measurements of the cavity were executed prior to the material injection and after 20 and 40 cycles of injection. Afterwards, precise measurements were made using CMM, three times in each phase after the removal of the cavity insert from the mold plate. This process is envisioned to deliver evidence on the everlasting cavity distortion and thus on the insert material stability.

**4.6 Mechanical and DSC analyses-** The samples were tested using an Universal testing machine at ASTM D 638 for tensile testing and ASTM D 790 (10 specimens each) for bending test at a speed of 5 mm/s (Figure 4.8). The impact study was performed with CEAST Resil impactor according to ASTM D 256 using hammer and Izod type. A notch (dimension A: 10.32 mm, angle: 45 ° and radius: 0.25 mm) with ten samples are prepared. The shore hardness (ASTM D2240) was measured and recorded by using a durometer in the broadest segment of the sample specimen. In this test, a sample fabricated with different variety of material insert was used. In addition, the results are reported in the form of standard deviation and mean deviation.

**Figure 4.8** Universal Tensile Testing Machine (EMICDL2000)

A TAQ20 Differential Scanning Calorimeter (DSC) in figure 4.9 was used to measure the percentage crystallinity of the mouldings. The sample mass was weighing 8 mg, the heating rate was  $10^{\circ}\text{C} / \text{min}$  and the nitrogen flow rate was  $50\text{ ml} / \text{min}$ . To avoid the skin region, samples were taken from the central region of the tensile specimens (Harris et al., 2004).

**Figure 4.9** TA Q20 Differential Scanning Calorimeter

A computer numerical control (CNC) Bridgeport mill was used in two experiments to determine whether post-processing of 3D printing dies helped to increase the ductility of molded tensile bars. In the other experiment the same CNC mill shown in figure 4.10 the edges of the molded tensile bars were machined as shown in Figure 4.11.

**Figure 4.10** CNC Bridgeport Mill used to post process the Digital ABS mold and tensile

**Figure 4.11** Milling the Edges of a Molded Tensile Bar

In DSC analysis, a single scan was performed for individual specimen to record the past thermal data of the polymer. In order to avoid heat due to mechanical cutting, the sample was cut with a hand cutter and extracted from the molded product. Before going to testing, samples were stored in desiccant crystals.

#### 4.7. Results and discussion

During the inspection of digital ABS insert a catastrophic failure was not observed. Figure 4.12 demonstrates the three dimensional surface outline of the printed digital ABS, after 20 shots and after 40 shots. Table 4.4 shows the surface quality data of the cavity considered. The "line" produced in the course of printing process are apparent in figure 4.12. As shown in figure 4.12, the peak-to-peak mean distance is 0.68 mm, and the waviness profile is shown at the mid of the measurement surface in figure 4.12 (a). The generated contours were duplicated on the molding surface and easily seen in Figure 4.14. In addition, no surface finishing was performed. Consequently, better surface quality in molding can be achieved by post processing of the insert cavity prior to injection for removing these 'lines'. Figures 4.12 (b) and 4.12 (c) and Table 4.4 illustrates that there is no significant change in the quality of surface profile after 20 and 40 injection cycles.

**Table 4.4** Digital ABS cavity surface quality

<b>Tensile cavity</b>	<b>Insert Stage</b>		
	As printed	20 shots	40 shots
Max. peak height ( $\mu\text{m}$ )	10.43	12.46	11.89
Roughness (Sq) = root mean square of height ( $\mu\text{m}$ )	5.192	5.472	5.033
Max. valley depth ( $\mu\text{m}$ )	15.45	14.02	13.69

(a)

(b)

(c)

**Figure 4.12** Three-dimensional surface profile of cavity as (a) printed, (b) after 20 shots and (c) after 40 shots

The peak attenuated slightly and the common surface profile (i.e. ‘line’) was upheld. In addition, the distance did not change either between peak and valley. The peak was anticipated to stabilize, but this did not happen. These results point out that the digital ABS is exceptionally stable against the number of trials and the number of injection parameters used. Table 4.5 clearly shows the dimension measurement results of the digital ABS cavity which is obtained by means of CMM after 20 shots and 50 shots and also Figure 4.15 confirms the same results. The dimensional specifications of the cavity including the length and breadth are slightly increased after 20 shots and decreased after 40 shots. The necessary clamping force to hold the mold closed is the main cause of the minor everlasting distortion (length and width reduction) at the end of the injection. To evade sparks, the mold structure inserts were mounted so that their surfaces touched against the metal plates. In contrast to dimensional characteristics that were reduced, there is slight increase in the cavity depth. The differences witnessed in all the three measurements are less and within the 3D printer precision.

**Figure 4.13** CMM Measurement

**Table 4.5** Digital ABS cavity CMM measurements

Parameters (mm)	stage		
	As printed	20 shots	40 shots
<b>Tensile Cavity</b>			
Length	118.325 <sup>(0.013)*</sup>	118.351 <sup>(0.067)</sup>	118.310 <sup>(0.024)</sup>

**Figure 4.14** 2D waviness profile (at 1.80 mm)

**Figure 4.15** Surface details of the tensile sample after 6 shots

Table 4.6 shows the variations in the dimensions of the molded parts. The table shows the mean size of 5 samples at the commencement, 5 injected into the middle (18-23) and the last 5 during the injection process. The sample length increases marginally as the number of shots increases (0.16% from the first sample to the last sample). A minor decrease in the dimension was detected in the mold cavity (Table 4.4) and is not identified in the sample. The primary reason is because of the usage of dissimilar resolutions of the measuring instruments and the different techniques.

**Table 4.6** Average Dimensions of PET samples after injection in the Digital ABS cavity

Features (mm)	Specimens		
	Shots 1 - 5	Shots 18 -23	Shots 35-40
Tensile specimen

Thickness	3.33 <sup>(0.02)</sup>	3.40 <sup>(0.04)</sup>	3.37 <sup>(0.01)</sup>
Width	13.23 <sup>(0.03)</sup>	13.31 <sup>(0.02)</sup>	13.26 <sup>(0.02)</sup>

**4.7.1 Mechanical properties and Crystallinity** - Table 4.7 shows the crystallinity of PET molded products of the two inserts used. For molded articles made with insert of digitalized ABS, the crystallation is lesser in comparison to the manufactured steel insert. The present outcomes were not anticipated, because the poor heat transfer rate in case of digital ABS reveals that the PET material solidify slowly in order to give polymer chains more time to self-organize (Segal and Campbell, 2001; Martinho et al., 2009). In addition, the heat transfer rate is increased with integration of cooling system inside the metal inserts. Baretta et al. (2007) found nearly the same values for PET injected into P20 steel feed (39.28%) and epoxy resin feed (39.18%) using similar calculation method of crystallinity. Salmoria et al. (2008) reported using another method 87.4% for a crystallinity of PET injected into an epoxy resin insert and 70.5% for PET injected into a steel mold. In both cases a PET homo-polymer is used. Crystallinity is not reported in both the cases, but Cunha et al. (1992) found several changes in the form of PET homo-polymer and PET copolymer.

**Table 4.7** PET specimens Crystallinity test results after injection in mold inserts

Insert material	SAE 1045	ABS
Heat of fusion $\Delta H$ (J/g)	81.24	71.65
Crystallinity $\chi$ (%)	39.27	34.59

Tables 4.8 and 4.9 illustrated the results of tensile and bending tests respectively. In the tensile test case, the material injected into the insert of digital ABS have a elasticity modulus of about 3% improved than its equivalent value for the molded object made with the SAE 1045 insert. Though, the tensile strength is quite similar for the inserts.

**Table 4.8** PET specimens tensile test results after injection in mold inserts

Insert material	SAE 1045	Digital ABS
UTS (MPa)	22.14 <sup>(0.47)</sup>	23.35 <sup>(0.46)</sup>
Modulus of elasticity (MPa)	896.68 <sup>(46.91)</sup>	916.54 <sup>(49.96)</sup>

In the bending test, a comparison of the molded parts produced by Digital ABS and SAE 1045 result the maximum tensile strength of about 24% and in the elastic modulus of about 19% is increased. Other similar studies have reported the increase in modulus of elasticity

**Table 4.9** PET specimens bending test results after injection in mold inserts

Insert material	SAE 1045	Digital ABS
Tensile strength (MPa)	23.35 <sup>(0.92)</sup>	27.75 <sup>(1.33)</sup>
Modulus of elasticity (MPa)	638.19 <sup>(22.51)</sup>	764.69 <sup>(39.34)</sup>
Yield strength (MPa)	17.87 <sup>(0.71)</sup>	20.69 <sup>(1.45)</sup>

The increase of tensile strength and elastic modulus of digital ABS and SAE 1045 is shown in table 4.9. The impact test results are shown in Table 4.10. The impact strength of the injected PET material into the digital ABS insert was about 32% more than the corresponding numerical value of the molded part manufactured using the SAE 1045 insert.

**Table 4.10** PET specimens impact test results after injection in mold inserts

Insert material	SAE 1045	Digital ABS
Impact strength (J/m)	40.78 <sup>(4.93)</sup>	54.47 <sup>(3.59)</sup>
Absorbed energy (J)	0.13 <sup>(0.02)</sup>	0.17 <sup>(0.01)</sup>
Absorbed energy %	12.96	15.67

Cunha et al. (1992) attracted the attention for the fact that the influence on impact strength is not only by crystalline but also by spherical and sized thickness. Therefore, for a better understanding of these effects, more detailed morphological analysis is required. Table 4.11 shows the hardness test results of PET specimens injected into the insert. No significant changes were detected.

**Table 4.11** PET specimens Hardness test results after injection in mold inserts

Insert material	SAE 1045	Digital ABS
Hardness (Shore D)	64 <sup>(0.7)</sup>	65 <sup>(0.5)</sup>

#### 4.8 Chapter Summary

This chapter examined the use of digital ABS material on RT applications, taking into consideration the surface stability along with the dimensional stability in the injection process and their effect on the ultimate molding properties. The outcome of the results reveal that a simple geometry, molding material and the total number of injections shots can be performed in a commercial injection molding machine with insert of digital ABS without any shattering calamity. After the fifty trails, there is a minor sufferings in the cavity, which is permanent distortion, however the surface quality is not affected and the surface maintained its original feature. Thus, digital ABS has shown a decent dimensional and texture stability for the duration of the plastic injection molding process. The digital ABS mold insert properties differed slightly from those of molded parts with metal inserts. First of all, a slight improvement in elasticity module and tensile strength is noted based on different studies performed. Second, there was a 30% or more significant improvement in impact strength is observed. The same hardness among was found in the molded articles produced using two different inserts.

## CHAPTER-5

### Volumetric Shrinkage Estimation of Benchmark parts

This chapter determines the volumetric shrinkage of common benchmark features for thermoplastic polyethylene terephthalate (PET) injection molded components made using digital Acrylonitrile butadiene styrene (ABS) mold. These benchmark features are found almost in each and every mold component. The effect of each benchmark feature on the dimensional characteristics of the parts produced is examined in this section. Therefore, twelve standard benchmark CAD model were selected with different geometric attributes. Subsequently, simulation analysis was performed on all CAD model using Moldflow® (MFA) simulation software. Additionally, regression analysis is applied to recognize the effect of injection molding parameters on the volumetric shrinkage of part made using rapid tooling mold insert of digital ABS material. It is found that maximum volumetric shrinkage (18.75 %) is observed for square pyramid frustum, conical frustum, and solid torus. On the contrary, hollow rectangular prism shows minimum shrinkage effect having 12.61 % of volumetric shrinkage. This study predicted that shrinkage is the main concern for these three geometric features (i.e. square pyramid frustum, conical frustum, and solid torus) and must be looked for its minimization. This work is extended in the next chapter for complex feature component. In that the component consist the standard benchmark features in a single part and the results are experimentally validated, by 3D scanner integrated with COMET plus and Inspect plus software. Since shrinkage estimation for digital ABS mold using Rapid Tooling technique has not been attempted before, therefore, this study provides guidance for the optimum parameter selection and assigning suitable shrinkage compensation values for digital ABS mold made using direct rapid tooling.

#### 5.1 Design and development of benchmark feature component

In this study, PET material is selected for simulation of the plastic injection molding process using digital ABS rapid tool mold insert. Properties of the selected polymer

material are listed in table 5.1. The selected twelve benchmark parts (figure5.1) consists of standard geometric features which are generally used in any industrial component.

**Figure 5.1** 3D Model of benchmark parts using Autodesk inventor solid modeling software

**5.2 Material selection and properties-** Digital ABS is selected for mold material. The properties of the digital ABS are detailed in chapter 3. The material PET is selected to inject inside the mold for development of test specimen. The input parameters and range of PET material is reported in table 5.1.

**Table 5.1** Input parameter of thermoplastic material polyethylene terephthalate (PET)

Parameter	Range Value	
Elastic Modulus (MPa)	1574.77	1530.86
Coefficient of thermal expansion ( $1/^\circ\text{C}$ )	0.00010	0.00015
Poisson ratio	0.35	0.44

Parameter	Value
Melt density Liquid (g/cm <sup>3</sup> )	0.73
Melt density Solid (g/cm <sup>3</sup> )	0.89
Shear modulus (Mpa)	523.90
Specific heat (J/kg- <sup>0</sup> C)	2740
Thermal conductivity (W/m- <sup>0</sup> C)	0.16

**Figure 5.2** Process flow diagrams for simulation and analysis

Figure 5.2 shows the process flow diagram describing a sequence of steps for modeling and simulation of twelve benchmark parts using Autodesk inventor 3D modeling and Moldflow® (MFA) software respectively. Tooling design requires (i) orientation of the

parting plane (ii) scaling the model to accommodate for shrinkage allowance according to molten material selection (iii) generating draft angle (iv) splitting the part geometry at parting line to create die and cavity shapes.

The value of shrinkage ratio is different for different material and depends upon type of molten plastic material. One of the significant steps for modeling the benchmark part is to apply shrinkage ratio actually for particular material. Standard benchmark CAD model in .stl file format is used as an input for simulation study.

Table 5.2 and 5.3 shows the mold material (Digital ABS) properties and default simulation setting parameter is considered for PET material respectively. The Moldflow® (MFA) analysis is performed after assigning a molten material with similar analysis for all benchmark parts throughout the injection molding process. The material used to perform this experiment is commercially available for injection molding of products, refer table 5.1.

**Table 5.2** Input parameter of mold material (Digital ABS)

Thermal Properties		Mold mechanical properties	
Parameter	Value	Parameter	Value
Mold density (g/cm <sup>3</sup> )	1.2	Elastic modulus (MPa)	3000
Mold specific heat (J/kg-°C)	1900	Poisson ratio	0.23
Mold thermal conductivity (W/m-°C)	0.27	Mold coefficient of thermal expansion (1/°C)	0.0000074

**Table 5.3** Simulation process setting parameter for Digital ABS mold

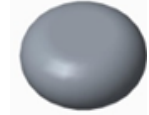

Melt temperature (°C)	240
Mold temperature (°C)	40
Packing pressure (MPa)	80
Packing time (s)	10
Maximum machine injection pressure (MPa)	180

**5.3 General considerations for design of standard benchmark parts** – Before development of core and cavity of all the standard benchmark features, the bounding box volume need to be calculated according to the input parameters. The input parameters for

bounding box volume for individual parts are bounding box dimension, height, draft degree, thickness; shrinkage value of injected material is reported in table 5.4

**Table 5.4** General consideration for bounding box volume of benchmark features

	Parts Images	Bounding Box Dimension (L×W×H) mm	H (mm)	Draft degree	Thickness (mm)	Shrinkage for Polyethylene material	Part volume before Shrinkage (mm)	Part volume after shrinkage (mm)	BB vol for BM parts

### 5.3.1 Geometric Attributes consideration

Geometric attributes are used to estimate the dimensional accuracy of the part features developed by a particular machine. The geometric features (shape and size) like volume of part, height, thickness and draft angle considered in this study. The weight of benchmark part model and the total weight (included sprue) of a same part model measured from the CAD software (considering the density value of PET molten material = 0.000738 g/mm<sup>3</sup>), the volume is obtained of all twelve benchmarks parts with using mass property function in Autodesk Inventor 3D modeling software.

**5.3.2 Volume Ratio (VR):** It is the ratio of the benchmark parts volume as obtained using the 1+S formulas for shrinkage factor calculation, Here ‘S’ denote shrinkage ratio to the bounding box volume. The bounding box volume assumes the maximum length, width, and height of the part geometry. The volume of all the reference parts considered is the same and is nearly about to 20000 mm<sup>3</sup>, where S = Shrinkage ratio (0.01 to 0.025).

$$V_R = V/V_B \quad (5.1)$$

**5.3.3 Thickness Ratio (TR):** This is the ratio of the minimum thickness of benchmark part to the maximum height of the same part.

$$T_R = T_{Min}/H_{Max} \quad (5.2)$$

**5.3.4 Draft Angle Ratio (DR):** It is the ratio of draft angle in parts to the standard draft angle consideration which is maximum up to 3<sup>0</sup> depending on the height of parts. In this study, the height constraint of all twelve benchmarks parts is same (20 mm).

$$D_R = \frac{D_A}{S_{DA}} \quad (5.3)$$

**5.3.5 Part Weight Ratio (WR):** It is the ratio of part weight to the total weight of the part.

$$W_R = \frac{W}{W_T} \quad (5.4)$$

**5.3.6 Quality Prediction Ratio (QR):** This is the ratio of quality prediction percentage to the desired quality (say 100 %) of all benchmarks parts.

$$Q_R = \frac{QP\%}{QP_{100\%}} \quad (5.5)$$

**5.3.7 Cycle Time Ratio (CTR):** This is the ratio of cooling time to the total cycle time.

$$CT_R = \frac{C_T}{TC_T} \quad (5.6)$$

**Table 5.5** Geometric attribute data compiled for regression analysis

Part Sr. No.	V	V <sub>B</sub>	V <sub>R</sub>	T <sub>Min</sub>	H <sub>Max</sub>	T <sub>R</sub>

12	0	3	0	14.57	15.543	0.937241

The above steps were involved in design criteria framework for Rapid Tooling injection molding process; it includes tooling design (die and cavity), simulation and the statistical technique. Finally, these results are validated by using regression method.

**5.4 Mold design for standard benchmark parts using Autodesk inventor 3D modeling Software** – In this section, the mold was prepared according to their part geometry. The stepwise methods are given below.

**5.4.1 Deign procedure to generate a core and cavity** -The defined work piece feature allows you to create a rectangular or cylindrical work piece that is a prerequisite for creating the core and cavity. For a rectangular work piece, set the length, width, height, and distance to control the shape of the work piece. For a cylindrical work piece, set the diameter and height of the work piece. The defined work feature offers product dimensions as design references. A preview function immediately displays the changes in the dimensions. Creating a satisfactory parting surface (interface) is a critical step in designing a successful injection molding tool. The right interface guarantees that the construction of core and cavity is suitable. It also ensures that the plastic part can be removed from the mold. In Inventor Mold Design, the interface is divided into two parts, the patch surface and the runoff surface also called drain surface.

**5.4.1.1 Procedure to create the patching surface**

Many plastic parts have holes or slots that need to be patched. It can be create a patch interface for an internal opening using the following patch tools:

**Figure 5.3** Procedure to create patching surface

In this process patch a plastic part with several holes. Then, use manual selection or auto-detection to create patch surfaces. After that, patch the loop with open end. For the existing surfaces, Use this option if you cannot create a patch surface with other patch tools. Although creating a patch surface is the most common command, the others are helpful if you have different requirements. After designing the work piece, define the runoff area. The runner off surface divides the work piece and removes the plastic part from the mold. To generate a runoff area the following tools: The Create runoff feature uses manual selection or automatic detection to generate a runoff surface. If automatic loop recognition is not appropriate for your needs, edit the loop and select it manually. If the automatic runoff surface that is created automatically is not appropriate, it can use the remaining methods to create a runoff surface. If it cannot create a runoff surface using these methods, then use “existing surface” function is the other option. It can create faces in the part and design environment and import them as a runoff surface. The Create Runoff Surface function manually selects or automatically determines the runoff cycle on the plastic part and creates a runoff surface on the loop. If you want to select edges in an area without edges, use the Split Face tool to divide the part. Then select the resulting edges to create a runoff loop.

**Figure 5.4** Create runoff areas

A single runoff loop is selected on the part. Sometimes the recognized runoff loop is correct, but the surface based on the runoff loop is not generated accurate. In this case, change the direction of the surface to obtain a satisfactory runoff area. If the design of the part is complex, it takes more time to detect the runoff loop.

### 5.5 Moldflow Simulation Results and Analysis for the Benchmark Parts

Simulation is performed on Moldflow® (MFA) FEM software. Simulation study was done to evaluate and advise the injecting location, observed defects (air trap, weld lines, shrinkage, warpage), cycle time (fill time, packing time, cooling time, mold-open time) in order to be able to improve the accuracy in the injection molded parts made using Digital ABS Rapid Tooling Mold Inserts. In this process, Solid Geometry imports mesh from Parasolid®-based CAD systems, Autodesk Inventor software, and STEP universal files. Then, scan imported geometry and automatically fix errors that may occur during translating a model from the CAD software. After that review, correct, repair, and

make it simple; solid models carried from 3D-CAD systems to prepare them for simulation. Then, perform 3D simulations for all features using a fixed, tetrahedral finite element mesh technique. The result of the simulation study for a single benchmark part is shown in figure 5.6 as an example; similarly it is preceded for the rest of the benchmark parts reported in figure 5.7.

**Figure 5.8** Regression graph for volumetric shrinkage percentage

## 5.6 Chapter Summary

Linear regression models are most powerful statistical techniques for solving optimization problems and can influence complicated relationships among several variables. They help in explaining the correlation between dependent variable (volumetric shrinkage), with determined values of one or more independent variables (VR, TR, DAR, WR, QPR, CTR). To model the process, a mathematical function with a linear polynomial curve is used. Therefore, correlation coefficients, R\_ Square value, of the equations for volumetric shrinkage of 96.37%, calculated which explores the volumetric shrinkage of a linear relationship between the simulation data and the expected values from the regression model. Based on this  $R^2$  test, quadratic polynomial models are best fitted for the output. The normal probability distribution of shrinkage defect residuals of the ABS mold shows that the residuals are mostly fall on a straight line, with the errors being normally distributed and obviously showing that the resulting quadratic model is precisely more accurate. It can easily notice from the Table 5.7, highest volumetric shrinkage percentage (18.75 %) results are obtained for square pyramid frustum, conical frustum, and solid torus, and the lowest volumetric shrinkage percentage of 12.61 % is achieved for the hollow rectangular prism, which is investigated through Moldflow® (MFA) simulation software.

Hence, from the above literature it can be determined that, the process of rapid tooling plays a significant role in injection molding and simultaneously this process is an important issue also. The exact numerical simulation of this process is a challenging task. In this work, the polyjet technology was adopted to manufacture the component by injection mold inserts. The work is carried out for complex feature component in the next chapter, where these benchmark features are integrated in a solitary part and it is experimentally checked.

## CHAPTER- 6

# Volumetric Shrinkage and Warpage Estimation of Complex Parts

This chapter deals with the study of volume shrinkage and warpage results of complex parts that is extended work of previous chapter for benchmark parts. For this purpose an electronics component relay is considered as a sample produced from digital ABS mold integrated with straight cooling channels. The resulting volumetric shrinkage and warpage is investigated for various benchmark features integrated in a solitary component. The PBT/PET molten material is used to inject into the mold to produce the required constituent. A systematic methodology is proposed for analyzing volumetric shrinkage and warpage in an injection molded part having a thin shell structure during the injection molding process. Initially, the effects of the injection process parameters on shrinkage and warpage for various wall thicknesses were examined using Taguchi method. The shrinkage and warpage values were found by Moldflow insight software. The shrinkage and warpage was analyzed and predicted by the acquired mathematical models for the individual effects of all parameters. The results of performing confirmatory experiments and analysis of variance (ANOVA) ensure that the quadratic models of shrinkage and warpage are well fitted with the simulated values at the optimum value.

### **6.1 Development of Core and Cavity for complex feature component**

Digital ABS is used in the present study to make mold inserts with cooling channel to improve the part quality and mold efficiency. The straight cooling system is inserted in mold. The results that belong to cooling system were taken as (cooling channel diameter: 8 mm, the distance between cooling channel and the part: 8mm, No of straight cooling channels: 4, the distance between the channels centers: 8 mm).

For this study, the diameter of cooling channel and gate location are considered as design factors along with melt temperature, packing pressure and packing time as process parameters are used to model and optimize the results of shrinkage and warpage for a

relay cover. The resulting volumetric shrinkage and warpage is investigated for the benchmark features that are mounted in the component.

**Figure 6.1** Development of Core and Cavity for test part

## 6.2 Design of injecting plastic part

An electronic part component (relay) as shown in figure 6.1 was considered as a sample for analysis contains complex geometry. It was designed with Autodesk Inventor 3D modeling software. The dimensions of the part component are 72 mm × 34 mm × 48.5 mm. Three different wall thickness 0.8 mm, 0.9mm and 1 mm was considered for the analyses.

### 6.2.1 Best gate location

An analysis of the best gateway location was done in the MPI software to determine where to place the location of the gateway in simulations. Figure 6.2 shows the outcome of this analysis. Based on the result of the analysis using MPI software, it is required to put the gate to the red colour area as in figure 6.2.

**Figure 6.2** Result of best gate location analysis

### 6.3 Employed parameters

Some of the important processing parameters such as filling time, mold temperature, gate dimensions and locations, melt temperature, packing pressure, and packing time are always used in injection molding. The mold temperature, melt temperature, packing time, packing pressure respectively are the most influential factors to determine warpage defects. In this study, the injection parameters are considered as Melt temperature, packing time and packing pressure for digital ABS material.

The operating parameters which were used for the shrinkage and warpage analysis for this work are melt temperature, packing pressure, packing time. The parametric values for the analysis are shown in Table 6.1.

**Table 6.1** Optimal process parameters and levels

Levels	A: Melt temperature (°C)	B: Packing pressure (MPa)	C: Packing time (s)
1.	254	25	10
2.	266	30	15
3.	278	35	20

In Table 6.1, the values for the melt temperature, the packing pressure and packing time were taken from MPI 4.0 database. Here, the mold temperature is not considered because of its poor thermal conductivity, the heat transfer rate is very slow between the mold and the part. The mold takes more time to cool Hence; the defective parts are produced which need to be improved. To provide uniform and rapid cooling, a straight cooling channel is inserted inside the mold and simultaneously employs a supercritical CO<sub>2</sub> cooling spray on plastic mold to decrease the plastic mold temperature to 9°C before each shot. Later, the experiments were performed by molding with PBT/PET in the Digital ABS tool at a slower injection speed and a lower melt temperature.

### 6.5 Taguchi method

In this study, L9 ( $3^2$ ) orthogonal array is shown in Table 6.2 which is employed with design of experiment method. Analyses were performed after locating the values from Table 6.4 to Table 6.5.

### 6.6 Analysis for injection molding

The analyses of the component has been done by MPI software. The type of the mesh was “3D tetrahedral”. The model consists for analysis is 23374 elements. PBT/PET materials were used for three different thickness values. MPI software is used to determine the best gate location to inject the molten material. The analysis has been done for cool +fill+ warp using MPI software. The total warpage and shrinkage values were found in X, Y and Z co-ordinates.

**Figure 6.4** the exact gate location and finite element mesh

### **6.7 Analysis of three various wall thickness for PBT/PET materials**

Analysis has been performed for three various wall thickness values 0.8, 0.9 and 1.0 mm using PBT/PET materials. Table 6.3 shows the results of these analyses. The shrinkage and warpage characteristics for these three values can be compared from these results. To evaluate the results of the analysis for PBT/PET materials, statistical methods have been used for these thickness values. The analyses were performed by Regression and ANOVA methods using MINITAB software for these values.

### **6.8 Regression analysis method**

Regression analysis is the most versatile tool employing in research area. The basic concept of this technique is determining the effect of various factors on the outcomes during performing the experiments. The replication of the experiments may be one or more and the factors may be direct or indirect. The observation and the effected parameters must be shown with mathematical model while doing Regression analysis. The regression model also called generated model. The mathematical model includes variables while investigating the regression analysis. The variables must be able to count and can be measure also.

### 6.9 Warpage and shrinkage analysis for results evaluation

For the consideration of warpage as a mathematical model, more than one variable can be accepted that directly or indirectly effected in shrinkage and warpages. Now, for PBT material of 0.8 mm wall thickness the minimum and maximum warpage values are 0.801mm and 0.9432 mm respectively. Similarly for PET material for same wall thickness, the minimum and maximum warpage values are 0.5701mm and 0.682mm. For 0.9 mm wall thickness the minimum warpage for PBT material is 0.7441 mm and maximum warpage is 0.9367. For PET, it is 0.5546 mm is minimum and 0.66 mm is maximum. For 1.0 mm wall thickness, they are 0.7491mm minimum and 0.8082 mm is the maximum for PBT whereas, for PET it is 0.6105 mm and 0.6797 mm respectively.

Similarly, the minimum and maximum shrinkage of PBT material for 0.8 mm wall thickness is 15.17mm and 16.1 mm respectively. For PET material, it is 13.30 mm is the minimum and 14.30 mm is the maximum value. For 0.9 mm wall thickness, the minimum shrinkage for PBT material is 14.14 mm and 16.59 mm is the maximum shrinkage. Next, for the same thickness of PET material, it is 13.71 mm is the minimum and 14.76 mm is the maximum shrinkage. For 1 mm wall thickness, the minimum shrinkage for PBT material is 16.12 mm and maximum shrinkage is 17.45 mm. For PET material it is 13.35 mm is minimum and 14.38 mm is the maximum value of the shrinkage. The most influential factor for warpage and shrinkage of ABS material is packing pressure.

**Table 6.4** Regression model for warpage and the R<sup>2</sup> values for PBT/PET material

Thickness (mm)	Regression model for PBT material	R <sup>2</sup> %
0.8	Warpage = 0.925 - 0.0322 Melt temp - 0.0336 Packing Pressure + 0.00377 Packing Time	90.9
0.9	Warpage = 1.05 - 0.0626 Melt temp - 0.0429 Packing pressure + 0.00348 Packing Time	96.9
1.0	Warpage = 0.831 - 0.0265 Melt Temp + 0.00098 Packing Pressure - 0.00328 Packing Time	97.6

  

Thickness (mm)	Regression model for PET material	R <sup>2</sup> %
0.8	Warpage = 0.740 - 0.0307 Melt Temp - 0.0269 Packing Pressure - 0.00180 Packing Time	78.8
0.9	Warpage = 0.711 - 0.0290 Melt Temp - 0.0233 Packing Pressure - 0.00215 Packing Time	98.3
1.0	Warpage = 0.658 - 0.0216 Melt Temp + 0.00605 Packing Pressure + 0.00280 Packing Time	98.7

**Figure 6.5** Normal probability plot for warpage of 1 mm wall thickness

The results of the Anderson-Darling (AD) standardity test are shown in Figure 6.5 for the respective distortion of PBT and PET for residues of 1 mm wall thickness. Since the p-value of the normality diagrams is over 0.05, it means that the rest follows the normal distribution, and the given models are suitable for practical technical applications. From the response surface plot (see Figure 6.6) it is observed that the warpage first decreases and then increases with increasing layer thickness for PBT and PET materials.

**Figure 6.6** Typical response surface plots

**Table 6.5** (a) and (b) Regression model for Shrinkage and the  $R^2$  values for PBT and PET material

Thickness (mm)	Regression model for PBT material	$R^2$ %
0.8	$VS = 14.4 + 0.800 \text{ Melt temp} + 0.0250 \text{ Packing Pressure} + 0.0233 \text{ Packing Time}$	98.6
0.9	$VS = 15.5 + 0.647 \text{ Melt temp} - 0.0083 \text{ packing Press} + 0.0067 \text{ Packing time}$	99.6
1.0	$VS = 12.8 + 1.09 \text{ Melt temp} + 0.0800 \text{ Packing Pressure} + 0.0933 \text{ Packing Time}$	99.6

Thickness (mm)	Regression model for PET material	$R^2$ %
0.8	$VS = 13.0 + 0.483 \text{ Melt temp} - 0.0483 \text{ Packing Pressure} + 0.00333 \text{ Packing Time}$	99.7
0.9	$VS = 13.3 + 0.493 \text{ Melt temp} - 0.00167 \text{ Packing Pressure} - 0.00833 \text{ Packing Time}$	99.9
1.0	$VS = 13.1 + 0.452 \text{ Melt temp} - 0.0550 \text{ Packing Pressure} - 0.0100 \text{ Packing Time}$	100

**Figure 6.7** Normal probability plot for volumetric shrinkage of 1 mm wall thickness of PBT and PET standardized residuals at 95% of confidence interval

Similarly, the results of the Anderson-Darling (AD) normality test are shown in Figure 6.7 for the respective shrinkage of PBT and PET for a 1 mm thick residue. Since the p value of the normality plot has been found to exceed 0.05, this means that the residues follow a normal distribution and the given model is suitable for practical engineering applications.

To determine the results obtained from the analysis is acceptable or not for PBT/PET materials for three thickness values regression analysis method is used. The model above is used to predict shrinkage and warpage values within the range of factors studied from the regression model and the  $R^2$  value of warpage and contraction depends on the wall thickness analysis. Here, the  $R^2$  values is more than 90%, it is acceptable. During warpage and shrinkage analyses, three injection parameters were used. These parameters are melt temperature, packing pressure and packing pressure. After finding the shrinkage and warpage values, the effect of each injection parameter was examined for each material.

**Figure 6.8** Typical Response Surface plots for shrinkage

The typical response surface of typical interactions is depicted in Figure 6.8. It is easy to recognize that the shrinkage value increases as wall thickness increases.

**6.10 Experimental verification-** In this section, inspection of the part developed by ABS mold and mold inserts is performed experimentally on injection molding machine.

**6.10.1 The evaluation of rapid tooling by developing the test mold-** A special geometry part was designed to depict the effect of rapid tool mold properties. The effect of mold design, mold materials, various technological parameters, and geometrical attributes can be easily estimated by developed parts.

**6.10.2 Manufacturing of the rapid tooling mold by polyjet technology**

A mixture commonly used for AM IM tools is a material called Digital ABS. It is made by mixing two different polymers in the machine (Gibson, 2015; Stratasys, 2017a). To produce the rapid tooling mold inserts, An rapid prototyping machine (Object Alaris 30 ) is used. Thin 28  $\mu\text{m}$  layers having resolution of 600 $\times$ 600 $\times$ 900 dpi is used in Alaris 30 printers. The mold inserts were printed using support material (Fullcure705) and building material (Fullcure720) which was removed by NaOH (5%) solution refer Chapter 3 for working principle of Polyjet Direct 3D printing Figure 3.12.

### 6.10.3 Process parameter and Material selection for Injection molding Experiments

For the test, an advance injection molding machine Arburg 370S 700 – 290 having screw diameter of 30 mm was used. The operating parameters like Injection volume ( $44 \text{ cm}^3$ ), the injection rate ( $50 \text{ cm}^3/\text{s}$ ), the switch –over point ( $12 \text{ cm}^3$ ), clamping force (50 t), and the pressure limit (400 bar) and melt temperature ( $200^\circ \text{ C}$ ) was used. Coolant temperature was  $20^\circ \text{ C}$  in the case of polyjet mold.

**Table 6.6** Plastic Injection Molding Machine

Operating parameters	
Temperature- $210^\circ \text{C}$	Clamp force – 15 KN
Injection pressure-300 bar	Shot size – 60 cc
Holding pressure-1000 bar	Cooling time – 300 sec
Holding time – 8 sec	

**Figure 6.9** Arburg 370S 700 – 290 injection molding machine

**Figure 6.10** 3D polyjet mold mounted on for experiment

**Figure 6.11** Cracked mold after performing 150 shots

During the experiment the PRT mold breaks after 140-150 shots see figure 6.11. In all instances was that the part adhered to the surface of the mold cavity and prevented part extraction. Regardless of the application of the release agent, the part would be fused to the mold so that the part could not be extracted without destroying the mold cavity. At the time of extraction process, the mold usually chip and destroys the gate or surrounding

parting line, making the insert unusable. So, to overcome this problem, the mold is inserted inside a metallic core and cavity, and performed the experiments on plastic injection molding machine to improve the strength of the mold and getting more number of trials to develop the parts refer figure 6.12.

**Figure 6.12** ABS mold insert with metal die

### 6.11 Comparison of the outcome of simulation results with experimental data using 3D scanners

The Steinbichler Comet L3D enables non-contact optical scanning. The version used for the comparison is with resolutions of 2 MPX and  $1600 \times 1200$  pixels. With this portable scanner, a scanning head is mounted on a tripod during scanning. The Rotary table can be used for positioning (rotating) measurement data. The Basic change of scanned data, comparison with model and export in STEP, IGES, and STL format (Figure 6.13) have to be done by using software (COMET PLUS , INSPECT PLUS).

**Table 6.7** Operating parameter Steinbichler Comet L3D

Resolution of camera [dpi]	1600×1200
Field Measurement [mm]	400
Volume Measurement [mm <sup>3</sup> ]	400×300×250
Point to point distance [μm]	250

Complex  
feature part

**Figure 6.13** Steinbichler Comet L3D during scanning

**6.12 Scanning methodologies-** For study the geometric features of the developed complex part is inspected in this section using 3D scanner operated with softwares.

**6.12.1 Environmental Conditions** – During scanning it was required to maintain the basic parameters of the environment such as temperature, humidity, lightning etc. without changing it. In order to stabilize thermal properties it was essential to leave the scanned sample in the room where the scan was done. If the object has a glossy surface, it is essential to repair it with a powdery choke sprayed on it. As a result, a position marker is placed on the object and / or its surroundings.

**Figure 6.14** Deviation between 3D scan and CAD model

The Independent assessment of the deviations between the CAD model of the sample and the obtained mesh was performed. The BEST-FIT function is used for comparison of a 3D scan against the model, where the rapid, rough alignment is followed by a precision adjustment. The evaluation distance is set as 1 mm. In graphic processing, the color gamut was set to  $\pm 0.2$  mm; Values over and above this limit are indicated. Volumetric shrinkage estimation of benchmark features using Inspect plus software.

From figure 6.15 it can be easily recognized that 18.79 % is the maximum volumetric shrinkage found in cylinder feature and 11.57 % is the least volumetric shrinkage in hollow rectangular prism among all the features.

Highest Volumetric shrinkage = 18.79%    Lowest volumetric shrinkage = 11.57%

**Figure 6.15** Volumetric shrinkage of cylinder and hollow rectangular prism

### 6.13 Chapter Summary

The aim of this research work is to identify the exact location, where the possibility of shrinkage occurs in injection molded part, provide modification for better part quality. In this present change driven environment, determining the volumetric shrinkage percentage during design stage can help in comparing alternative design solution before the start of plastic part production. In this methodology, geometrical parameter involves such as volume, height, weight, draft angle, thickness, quality prediction percentage, total cycle time. With the help of integrating software package, CAD model is used for analysis with Moldflow® (MFA) simulation. Regression

analysis using twelve benchmark parts criteria were determining the coefficient of the geometric parameter equation in previous chapter. The regression equation can be employed in early phases of part lifecycle, significantly in design for manufacturability; the designer can easily estimate the volumetric shrinkage percentage of an injected part (from its CAD model), allowing comparison of alternate designs in term of the influence on die and cavity material. The outcomes were experimentally validated with 3D scanner integrated with inspection softwares.

## CHAPTER 7

# Optimization of Rapid Tooling Molded Complex Featured Component

The work of this chapter presents a systematic methodology to determine optimal injection molding conditions for minimum warpage and shrinkage in a thin wall relay part using modified particle swarm optimization algorithm (MPSO). Polybutylene terephthalate (PBT) and polyethylene terephthalate (PET) were injected in a thin wall relay component for different processing parameters: melt temperature, packing pressure and packing time. Further, simulation analysis using Taguchi's design of L<sub>9</sub> array is used to consider the interaction effects of the above parameters. A predictive mathematical model for shrinkage and warpage is developed for the above process parameters using regression analysis. An ANOVA analysis is performed to determine statistical implication within the injection molding parameters. The developed predictive model is further optimized using a newly developed MPSO algorithm and the process parameters values are predicted for minimizing shrinkage and warpage. The predicted values of warpage and shrinkage using MPSO algorithm are improved by approximately 30% as compared to the initial simulation values and comparable to previous literature results.

### 7.1 Introduction

The plastic injection molding (PIM) process is extensively applied for producing intricate shaped plastic parts with distinctive geometric features and has shorter production cycles. The PIM process is a repeated one which consists of the process beginning with filling and packing, after that cooling and at last ejection. Injection molding helps in producing products for computer, consumer electronic and communication (3C) i.e. computers that are portable and mobile phones. Generally, the 3C products are thin, light, short and small. However, with the increasing demand of more complex products having less wall thickness, the PIM process is prone to face more challenging tasks. Consequently, the quality of the parts produced using PIM process is affected by the appropriate selection of

the various process parameters and the mold design. In contrast, the inappropriate process parameter values led to produce part defects, resulting in long lead times and high cost.

Warpage and shrinkage are among the most important deficiencies used to measure the quality of injection molded components. Previous studies suggest that shrinkage and warpage are highly related to injection molding process parameters. The effect of gate geometry and packing parameters on the end part investigated, and it was found that a thinner gate gets a more uniform shrinkage in the process with the unchanged packing pressure. Galantucci et al. (2009) applied double skin model for investigating the warpage defect and further concluded that melt temperature was among the most influencing factor for minimizing warpage. Huang and Tai (2001) in their study applied computer simulation and experiment for analyzing the factor affecting warpage in a thin shell injection molded components. Tang et al. (2007) applied Taguchi method for minimizing the warpage in the design of improved plastic injection mold. Similarly, Taguchi and ANOVA are used in a study for obtaining optimal shrinkage injection molding conditions. The results suggested that optimized parameters reduce shrinkage by 1.244 % and 0.937 % for Polypropylene (PP) and polystyrene (PS), respectively.

Similarly, Park and Dang (2010) in their study suggests that runner and cooling channel geometry can improve the final quality of products. One specific study was found for minimizing the warpage in thin shell plastic parts by employing the genetic algorithm and response surface methodology. Hakimian and Sulong (2012) in their study applied Taguchi method to analyze the warpage and shrinkage in micro gears of polymer composites. Choi (1999) found that residual stress is a significant factor that influence the warpage and shrinkage defect in injection molded components. Liao et al. (2004) in their study provided optimum conditions for minimizing shrinkage and warpage problems. The cyclone scanner and polyworks software was used for determining the shrinkage and warpage problem. The packing pressure found to be the most influencing factors. Kikuchi and Koyoma (1996) have applied finite element method for studying the relation among warpage, part thickness and anisotropy. Othman et al. (2017) also optimizes the shrinkage and warpage in their study for composite material. In addition, effect of different process parameters is discussed in recent studies of Mohan et al. (2017) One recent study used simulation based methods for estimation of shrinkage and warpage in the injection molding

process. Some literature are also available which focusses on relating the polymer microstructure to molding ability, however, it is not in scope of the present work. Moreover, several studies found have used response surface methodology (RSM) individually or integrating with genetic algorithm (GA) for determining the interaction and relationship among factors and process parameters. Similar studies have been found that uses neural model, modified complex method, grey-fuzzy logic for thin shell feature for optimization of warpage in different thermoplastic parts.

Generally, the warpage problem in thin-wall injection molded plastic parts has been reported in many literatures. As thickness of the part decreases, the shrinkage defect becomes even more complex and causes significant warpage of the plastic component. However, few of them have shown the effective processing variables and their optimization for the dimensional shrinkage and warpage minimization under high-speed injection molding process. The past literatures have used only GA for the determination of optimal injection molding conditions. The current study takes into consideration a newly developed modified particle swarm optimization (MPSO) algorithm for optimal injection molding process parameter determination.

In this study, a systematic methodology is presented using regression analysis and a newly developed MPSO algorithm for determining the optimum process parameters. The Particle Swarm Optimization (PSO) algorithm has proven to be a successful tool for resolving optimization applications because of the simplicity of the concept with less parametric adjustments compared to other nature inspired optimization algorithms. However, the usual PSO faces some disadvantages. For example, a fragile local search that can lead to an inclusion of local minima that affect the convergence performance, leading to uncertainties in the obtained results. To improve PSO's exploitation capabilities, the MPSO is offered by Pathak et al. (2018) which is modified version of classical PSO. Based on the new improved particle position, which is different from global and local best positions. An effective greedy selection procedure is employed to get a better position to decide on a new position and a candidate based on fitness values.

Furthermore, a real life case study of an electronics component relay is considered for injection molding process. The PBT/PET molten material is injected into the mold to

produce the required constituent. An effective methodology is proposed for analyzing volumetric shrinkage and warpage in an injection molded part having a thin shell feature at the time of injection molding process. Initially, the effects of the injection process parameters on shrinkage and warpage for various wall thicknesses were examined using Taguchi method. The shrinkage and warpage values were found by Moldflow insight software. The results of confirmation experiments and analysis of variance (ANOVA) assure that quadratic shrinkage and buckling models are well equipped with simulated values at the optimum value. The quadratic shrinkage and warpage models are well fitted with simulated values at the optimum value. The analysis of dimensional behavior including shrinkage and warpage have been performed and the developed mathematical models helps in prediction of the specific effects of different parameters.

## **7.2. Experimental Details**

An electronic relay part, with an overall dimension of 72 mm × 34 mm × 48.5 mm was designed in Autodesk inventor 3D modeling software and was used as a model, using a 3D mesh type. The analytical model consists of 29, 812 elements. The analysis were performed using three thickness values of 0.8, 0.9 and 1.0 mm. Figure 7.1 shows the mesh file of relay component with the cooling channels. The default values were determined using an injection molding machine (maximum machine injection rate, 6000 m<sup>3</sup>/s) and acrylonitrile butadiene styrene (ABS) mold material (mold density, 1.5 g/cm<sup>3</sup>; mold specific heat, 1300 J/kg °C). The injection molded electronic relay was either made of PBT or PET material, due to wide application of these materials in academic and industries. The PBT and PET polyesters are important commercial material having many attractive properties. They have high strength and toughness, good abrasion and heat resistance, good chemical resistance, low creep at elevated temperatures, and excellent dimensional stability, particularly when glass-fiber reinforced. Both are semi-aromatic. These are amorphous thermoplastic materials when solidified by rapid cooling or semi-crystalline thermoplastic materials that are easily formatted and thermoformed. The physical properties of these materials are summarized in Table 7.1, acquired from Moldflow Insight library.

**Figure 7.1** Electronic relay mesh file with cooling channel

**Table 7.1** Physical properties of PBT/ PET material

Property	PBT	PET
Melt density (g/cm <sup>3</sup> )	1.31	0.72 - 0.76
Solid density (g/cm <sup>3</sup> )	-	0.86 - 0.96
Mold temperature (°C)	40 - 60	80 – 120
Melt temperature (°C)	220 - 280	265 - 280
Poisson ratio	0.3902	035 – 0.45
Material structure	Semi-crystalline	Amorphous

The parameters considered for shrinkage and warpage analyses are melt temperature (A), packing pressure (B) and packing time (C). The values of these parameters are provided in Table 7.2. The injection time was fixed at 3 seconds for all experiments. An L<sub>9</sub> (3<sup>3</sup>) orthogonal array was selected for the experimental design for each of the three factors. The three levels for the three factors were identified during the 9 experiments (see Table 7.3). The signal-to-noise ratios (S/N) for every trials were determined using the signal-to-noise ratios (S/N) for every trials were determined using

$$\frac{S}{N} = -10 \log \left[ \frac{1}{n} \sum_{i=1}^n y_i^2 \right] \quad \text{-----} \quad [7.1]$$

where  $n$  is the number of shrinkage and warpage data sets (equal to 9) and  $y_i$  is the shrinkage and warpage value for the  $i^{\text{th}}$  data sets. The ANOVA analysis is performed using the Minitab software.

**Table 7.2** Process Parameters and their levels

### 7.3 Results

The Taguchi method was applied to predict the effect of injection molding process parameters on the shrinkage and warpage. The measured values of shrinkage and warpage and the signal-to-noise ratios are measured and reported in Table 7.4. The signal-to-noise ratio is an important quality indicator that researchers used to determine the influence of varying a particular parameter on the performance. For the current study, smaller the better

characteristic was selected when calculating the S/N ratio, which is based on equation 7.1, as shown in Table 7.4. It was found that the best process parameter value can be determined by selecting the level with the best values at each factor. Figure 7.2 illustrates the variation of the S/N ratio of warpage and shrinkage for different PBT and PET material. Based on shrinkage results in Table 7.4 and Figure 7.2 (a), it was found that PET material had higher S/N ratio (-6.02) value than the PBT material, because it exhibits least shrinkage as compared to PBT. Similarly, the warpage result shows that PET also has least warpage in comparison to PBT warpage values. It was clearly seen from the results that PET material is better for producing relay component in comparison to PBT material due to its least shrinkage and warpage.

**Table 7.4** Shrinkage and warpage values of PBT and PET material

Exp. No.	PBT		PET		PBT		PET	
	Shrinkage %	S/N ratio	Shrinkage %	S/N ratio	Warpage (mm)	S/N ratio	Warpage (mm)	S/N ratio

**Figure 7.2** Variation of the S/N ratio of (a) Shrinkage (b) Warpage

For further analyzing the obtained results and determining the significance of each parameter, regression analysis and ANOVA test was performed. These analyses were performed on Minitab V14 software. Due to change in response statistics drastically with the control parameters, it is very challenging to develop an analytical model. The regression analysis may be the solution to this problem which is useful in searching the effect of factors to an event while examining that event. There may be factors which are either direct or indirect. The regression analysis is worthwhile when the focus is on determining the relationship between dependent and one or more independent variables. While using multiple regression analysis, the equation of the form given below is used to explain the relationship between the independent variables  $X_1$ ,  $X_2$  and  $X_3$  and the response variable  $Y$ .

$$Y = \beta + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_{11} X_1^2 + \beta_{22} X_2^2 + \beta_{33} X_3^2 + \beta_{12} X_1 X_2 + \beta_{13} X_1 X_3 + \beta_{23} X_2 X_3$$

Based on the above generalized regression model, the following analytical model was obtained for shrinkage of PBT and PET in the form of coded unit:

$$\text{Shrinkage (S1)} = 0.326440 + 0.201507X_1 - 0.034872X_2 + 0.065912X_3 - 0.003173X_1^2 - 0.029771X_2^2 - 0.004712X_3^2 + 0.033242X_1X_2 + 0.023560X_1X_3 + 0.048322X_2X_3$$

$$\text{Shrinkage (S2)} = 0.462270 + 0.305915X_1 - 0.048202X_2 + 0.079210X_3 - 0.002320X_1^2 - 0.041725X_2^2 - 0.003712X_3^2 + 0.045902X_1X_2 + 0.043450X_1X_3 + 0.054721X_2X_3$$

In addition, the model significance is further validated using ANOVA analysis. The ANOVA results for PBT and PET material are shown in Table 7.5 and Table 7.6 respectively. The model was built for 95% confidence level. The correlation coefficient ( $r^2$ ) of the developed analytical models for PBT and PET was found to be 0.973 and 0.962 (nearer to the ideal value of 1). The adequate value of regression coefficient indicates that the model is significant and further analysis and predictions can be performed. All the linear, square and interaction terms have significant effect on the response output. It was clearly seen from Table 7.5 and 7.6 that the F-value is significantly higher for both the ANOVA table, indicating that the model is significant. There is only a chance of 0.05% that such a high model F value might have occurred due to noise.

**Table 7.5** ANOVA result for PBT shrinkage model

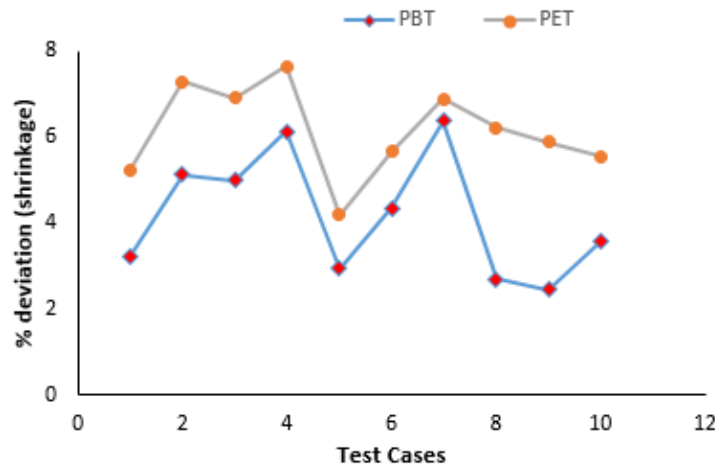

Source	DF	Sum of squares (SS)	Mean square (MS)	F-Value	P-value

Furthermore, the performance of the developed model of warpage for both materials was tested using ten randomly selected experiments other than the used in Table 7.4. The random values chosen from ten experiments are compared with the values obtained through developed analytical model. The results of percentage deviation in prediction of shrinkage for the PBT and PET material are shown in Figure 7.3. It was clearly seen from Figure 7.3, the percentage deviation in shrinkage prediction for PBT and PET are 3.56 and 5.55 respectively. However, the percentage deviation for shrinkage for PBT is less as compared to PET material. Similarly, the following analytical model for warpage was developed using non-linear regression model for both the material i.e. PBT and PET.

**Figure 7.3** Percentage deviation in prediction of shrinkage

$$\text{Warpage (W}_1\text{)} = 1.23966 + 0.772017X_1 + 0.005873X_2 - 0.347592X_3 - 0.027631X_1^2 - 0.000987X_2^2 - 0.012283X_3^2 + 0.000533X_1X_2 + 0.010937X_1X_3 + 0.000272X_2X_3$$

$$\text{Warpage (W}_2\text{)} = 1.78218 + 0.817812X_1 + 0.007291X_2 + 0.192205X_3 - 0.051140X_1^2 - 0.001723X_2^2 - 0.027831X_3^2 + 0.000612X_1X_2 - 0.033147X_1X_3 + 0.000721X_2X_3$$

The developed regression model significance is further tested using ANOVA analysis. The ANOVA results for PBT and PET material are reported in Table 7.7 and Table 7.8 respectively. The model was built for 95% confidence level. The correlation coefficient ( $r^2$ ) of the developed analytical models for PBT and PET was found to be 0.941 and 0.924 (nearer to the ideal value of 1). The adequate value of regression coefficient indicates that the model is significant and further analysis and predictions can be performed. Moreover, all the linear, square and interaction terms have significant effect on the response output. It was clearly seen from Table 7.7 and 7.8 that the F-value is significantly higher for both the ANOVA table, indicating that the model is significant. There is only a chance of 0.05% that such a high model F value might have occurred due to noise.

**Table 7.7** ANOVA Analysis for warpage PBT model

Source	DF	Sum of squares (SS)	Mean square (MS)	F- Value	P- value

Total	50	213.814				

Furthermore, the performance of the developed model of warpage for both materials was tested using ten randomly selected experiments other than the used in Table 7.4. The random values chosen from ten experiments and compared with the values obtained developed analytical model. The results of percentage deviation in prediction of warpage for the PBT and PET material are shown in Figure 7.4. It was clearly seen from Figure 7.4, the percentage deviation in warpage prediction for PBT and PET are 3.22 and 4.23 respectively. However, the percentage deviation for warpage for PBT is less as compared to PET material.

**Figure 7.4** Percentage deviations in prediction of warpage

#### **7.4 Modified particle swarm optimization algorithm**

In this section, the modified version of the classic particle swarm optimization algorithm to evaluate the developed analytic model in Eq. (7.3). Since the exploitability directly affects the quality of the results. The modified variant will help overcome the classic PSO disadvantage of low convergence due to lack of exploitation capabilities. The modified version will help to overcome the classic deficiency of PSO in low convergence due to the lack of ability to operate.

##### *7.4.1 Standard particle swarm optimization algorithm*

The basic particle swarm optimization is a population-based method proposed by Kennedy and Eberhart in 1995. PSO is modeled on simulating the social behavior of birds in a herd. PSO is initialized by randomly distributing each particle in the D-dimensional

search space. The performance of each particle is measured using a fitness function that depends on the optimization problem. Each particle  $i$  represented as:

$x_i$ , the current position of the particle  $i$

$v_i$ , current velocity of the particle  $i$

$p_i$ , personal best position of the particle  $i$

The personal best position is the best position the particle has reached so far. The adaptive function is highest at that position in the  $i^{\text{th}}$  particle. Here, the velocity behaves like a vector, and it helps to guide the particle from one position to another. Personal best position of  $i^{\text{th}}$  particle depending on time step  $t$  as:

$$\begin{aligned} P_i(t) &= p_i(t) && \text{if } f(x_i(t)) \geq f(p_i(t)) \\ &= x_i(t) && \text{if } f(x_i(t)) < f(p_i(t)) \end{aligned} \quad (7.3)$$

New position and velocity for  $i^{\text{th}}$  particle is updated at each iteration and expressed as:

$$v_i(t + 1) = v_i(t) + c_1 * r_1(p_i(t) - x_i(t)) + c_2 * r_2(g_i(t) - x_i(t)) \quad (7.4)$$

$$x_i(t + 1) = x_i(t) + v_i(t + 1) \quad (7.5)$$

$r_1$  and  $r_2$  are two independent uniformly distributed random numbers within given interval  $[0,1]$ .  $c_1$  and  $c_2$  are two accelerating coefficients whose value are generally 2 each for almost all applications,  $p(t)$  is the best position parameter of an individual particle and  $g(t)$  is global best position parameter of entire swarms. Shi and Eberhart (2000) introduced an inertia weight  $w$  into the velocity updating of the PSO that helps in controlling the scope of the search. Often,  $w$  decreases linearly from 0.9 to 0.4 over the whole iteration. High value of inertia weight helps in exploration whereas low value favors exploitation. The velocity update with inertia weight is shown in Eq. (7.6).

$$v_i(t + 1) = w(t) * v_i(t) + c_1 * r_1(p_i(t) - x_i(t)) + c_2 * r_2(g_i(t) - x_i(t)) \quad (7.6)$$

A new version of PSO is proposed in this thesis. The exploration and exploitation capabilities are two important factors that are included in the design of an optimization algorithm. Exploitation means using existing information while exploration generates a new solution in the search space. In PSO, the new solution is replaced by the old, without actually comparing which is better. This shows that the ability to use PSO is unavailable and is merely an exploration trend, making it difficult to find the best possible solutions.

Due to the lack of exploitation strategy, the classical PSO still has disadvantages, such as poor local search capabilities, and may lead to entrapment in local minimum solutions. To overcome all of these issues, the modified variant of the PSO algorithm generates a new swarm position and fitness solution based on the new search equations (7.7) and (7.8):

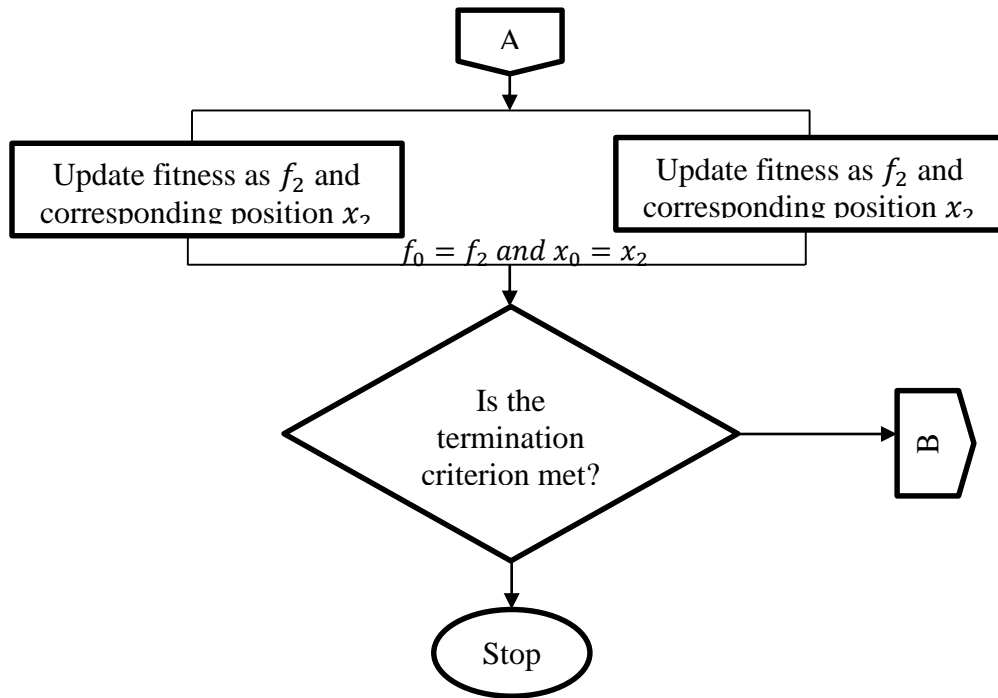

$$v_{new} = p_{best} + rand(g_{best} - p_{best}) \quad (7.7)$$

$$x_{new} = p_{best} + v_{new} \quad (7.8)$$

Where  $p_{best}$  the best position of the particle,  $g_{best}$  is is the best global position of the particle.  $rand$  is the random number between 0 and 1 that controls the speed at which the population evolves. The best sources of solutions to the current population are very useful to be used to improve the convergence performance. Also, Eq. (7.7), the new candidate solution can only drive around the best solution of the previous iteration. The proposed search and update equations described in Eq. (7.7) and (7.8) can increase the exploitation ability of the classic PSO. Any assortment strategy in the algorithm is commonly considered exploitation, since the fitness solution of the individual is used to determine whether a person should be exploited or not. Therefore, the MPSO particle swarms use a greedy selection process among two parallel fitness functions to update the best candidate solution, which also helps to improve the evaluation capability of the algorithm. The proposed transformation algorithm flowchart of the suspension is shown in Figure 7.5.

**Figure 7.5** Flowchart of modified particle swarm optimization (MPSO) algorithm

### 7.5 Optimization problem formulation

In this study, a mathematical model of shrinkage and warpage is minimized to obtain optimal values for melting temperature, packing pressure and packing time. The values of optimal parameters are required to improve the injection molding process

#### 7.5.1 Identification of design variables

The developed regression models for shrinkage and warpage consist of three important parameters such as melt temperatures, packaging pressure and packing time. These three parameters are design variables.

#### 7.5.2 Objective function and constraints

To improve the final accuracy of injection molded components, the shrinkage and warpage in  $S_1$ ,  $S_2$  and  $W_1$  and  $W_2$  needs to be minimized. The optimization problem now is to be formulated as:

$$\text{Minimize } f(t_m, p_p, p_t) = S_1$$

$$f(t_m, p_p, p_t) = S_1;$$

$$f(t_m, p_p, p_t) = W_1;$$

$$f(t_m, p_p, p_t) = W_1;$$

In order to solve the optimization problem, a computer code that implemented the objective function and modified PSO as a solver in Matlab R2014a is developed.

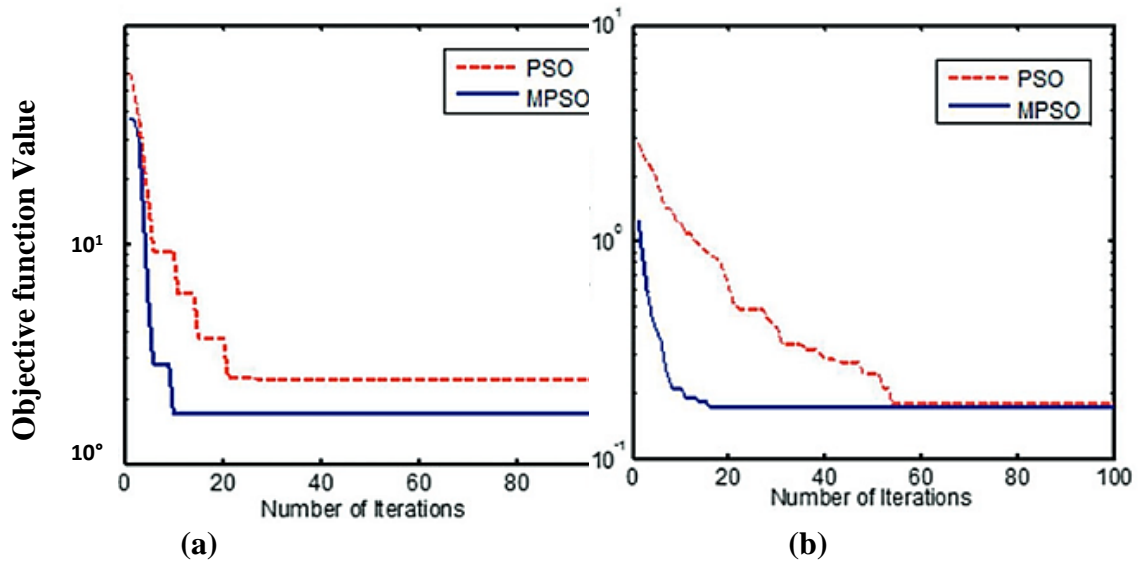

The MPSO program used different settings of PSO parameters to predict the values of the injection molded parameters and to achieve minimized shrinkage and warpage values for the final components. To demonstrate the effectiveness of the proposed MPSO algorithm, its results are compared to those found from the standard PSO algorithm. The parameters for both algorithms are set as follows:  $c_1, c_2 = 2.05$ , number of population size = 10.

### 7.6 Discussion

The results predicted to minimize shrinkage and warpage with PSO and proposed MPSO for optimized values of melt temperature; packing pressure and packing time are shown in Table 7.11. From Table 7.11, it can be seen that the predicted values of the injection molded relay component by the MPSO algorithm provide a significant improvement over the PSO results as well as the simulation results by 36.47% for the PBT shrinkage and 19.31% for the PBT warpage, respectively demonstrate. Similar results are found for PET material having shrinkage reduction of 30.73% and warpage reduction of 28.79%. The convergence plot of the MPSO algorithm compared to the standard PSO for PBT material is depicted in Fig. 7.6. It can be observe from Figure 7.6 that the MPSO algorithm requires only 20 iterations to converge to the optimal solution compared to the classical PSO, which requires near about 60 iterations for the optimal solution. The low shrinkage and warping values confirm that the proposed MPSO algorithm provides better results. This improves the final accuracy and quality of the injection molded component and thus improves the result of the injection molding process.

**Table 7.9** Optimum parameters prediction using PSO and MPSO

Parameters	Melt temperature ( $T_m$ )		Packing pressure ( $P_p$ )		Packing time ( $P_t$ )		S1 (%)	S2 (%)	W1 (mm)	W2 (mm)
	PBT	PET	PBT	PET	PBT	PET	PBT	PET	PBT	PET
Initial value	278	252	25	34	10	12	1.9197	1.9145		
	266	252	25	28	15	18			0.1341	0.1608

**Figure 7.6** Convergence plot of (a) Shrinkage (b) Warpage of PBT material

To test the adequacy of the developed mathematical model and justify the use of newly developed MPSO algorithm, four simulation runs were performed for shrinkage (S1, S2) and warpage (W1, W2). The shrinkage and warpage results for PBT material is shown in Figure 7.7 and 7.8 respectively for the chosen parameter values. The collected confirmation trials data and their comparison with the envisaged values of shrinkage and warpage using MPSO algorithm is shown in Table 7.12. From Table 7.12, it is clearly seen that the predicted values of shrinkage and warpage are more accurate for the predicted model in comparison to the default simulation parameters. For further testing the adopted methodology, the results of shrinkage and warpage are compared with previous literature results for different polymer materials as tabulated in Table 7.13. It can be clearly seen from Table 7.13 that present study provide comparable results as compared to methods adopted in past research. The result confirms that the present methodology can be useful in plastic industries for producing accurate polymer products.

**Table 7.10** Confirmation simulation trials

S. No.	Parameters			Shrinkage		Warpage (mm)

## 7.7 Chapter Summary

This paper presents an integrated methodology for developing mathematical models and predicting the values of shrinkage and warpage by correlating them with process parameters of plastic injection molding process for developing the electronic relay component of PBT and PET material. The parameters considered for the prediction of shrinkage and warpage are Melt temperature, Packing temperature and Packing time. To find the optimum value of process parameters, the analytical model using regression analysis was developed. To further improve the optimum values a recently developed modified particle swarm optimization algorithm was used. The conclusions of the research are as follows:

7.7.1 The results of the ANOVA analysis, which conduct confirmatory experiments, show that the analytical models of shrinkage and warpage are properly well with the simulation values. The effects of all process parameters on the performance of shrinkage and warpage are analyzed by the obtained mathematical models.

7.7.2 The predicted response of injection molding process also shows an improvement, using a newly developed MPSO algorithm. The MPSO algorithm overcomes the absence of classical PSO exploitation by introducing the search equation to improve performance based on the best outcome of the prior iteration. In addition, a greedy selection technique is added to improve the classical PSO's exploitation ability. The improvement in shrinkage and warpage is around 30% as compared to the initial values of shrinkage and warpage.

## CHAPTER 8

# Conclusion and Future Work

This dissertation presents a novel framework for improvement in part quality produced by rapid mold inserts and performs contactless inspection of samples having standard and complex feature using a reverse engineering approach. The proposed work mainly consist the development of important features of complex part integrated with standard benchmark features and from manufacturing to inspection of the industrial parts is discussed in the remaining chapters of the work. Based on the work carried out and the results obtained, this work is divided into five parts.

In the first part of thesis the investigation of employability of rapid tooling (RTV /PRT) as a functional injection molding is done. This work reports on the shrinkage behavior of wax in RTV silicone rubber under the influence of operating parameters of wax injector. Similarly, in the next part of this chapter feasibility of polymer rapid tools for plastic injection molding is also examined. Due to inadequate robustness and stability in RTV and PRT mold is used as an alternative tool for plastic injection molding process. The stability and robustness of PRT mold is tested on hand injection molding machine and using reverse engineering technique followed by 3D scanner it is found that PRT mold is suitable for making the simple part feature. The outcome of the test sample is compared with CAD file and inspected with COMET plus software. The results were validated with conventional tooling. After finding the suitability of PRT mold, the mechanical and physical characterization of Digital ABS used in PRT mold reported in chapter 3. The mechanical properties of the test specimen were analyzed by tensile, bending and impact test as well as by measuring their hardness. The results reported provided for the digital ABS in this research showed good dimensional and surface stability during the injection process. These produced parts will be functional and can be used in industrial applications for long time.

The chapter 4 of this thesis deals with estimating the part defects i.e. volumetric shrinkage and warpage for thermoplastic Polypropylene (PP) injection molded components

made using digital Acrylonitrile butadiene styrene (ABS) mold. For this purpose, twelve standard benchmark CAD model were selected with different geometric attributes. Subsequently, a systematic methodology is followed for simulation analysis, the Moldflow® (MFA) software is applied on all CAD model to identify the effect of shape and geometry parameters on the performance of volumetric shrinkage. Further, statistical regression technique used for determining the percentage contribution of geometric attributes on volumetric shrinkage. The basic purpose of the proposed methodology is to estimate volumetric shrinkage according to geometric attributes employed with RP-based rapid tooling design injection molding process. For modeling the process mathematical function including linear polynomial curve is used. Therefore, correlation coefficients,  $R^2$  value, of the equations for volumetric shrinkage of 96.37%, calculated which explores the volumetric shrinkage of a linear relationship between the simulation data and the expected values from the regression model. Based on this  $R^2$  test, quadratic polynomial models are best fitted for the output. The normal probability plot of residuals for the shrinkage defects of ABS mold notice that the residuals generally fall on straight line. The errors are normally distributed and obviously show that the quadratic modal obtained is precisely accurate. It can easily notice from the reported result in this chapter, highest volumetric shrinkage percentage (18.75 %) results are obtained for square pyramid frustum, conical frustum, and solid torus, and the lowest volumetric shrinkage percentage of 12.61 % is achieved for the hollow rectangular prism, which is investigated through Moldflow® (MFA) simulation software.

This study provides guidance to the personnel for the optimum parameter selection and assigning suitable shrinkage compensation values for digital ABS mold made using direct rapid tooling.

Similarly in the next section of this chapter, the investigation of warpage and shrinkage analysis of thin section part produce through Digital ABS Mold of the results for benchmark parts was extended for a complex part for a new PBT and PET materials. Analysis has been performed for three various thickness values 0.8, 0.9 and 1.0 mm using PBT/PET materials. To evaluate the results of the analysis for PBT/PET materials, statistical methods have been used for three different thickness values. Regression and ANOVA methods are used for these analyses. The analyses were performed by using

MINITAB software. To predict the values of shrinkage and warpage within the limits of the factors studied from the Regression model, the  $R^2$  values for warpage and shrinkage are depends on wall thickness analysis. Here, the  $R^2$  values is more than 90%, it is acceptable. The results of the Anderson-Darling (AD) standardity test are shown in this chapter for the respective distortion of PBT and PET for residues of 1 mm wall thickness. Since the p-value of the normality diagrams is over 0.05 for warpage and shrinkage, it means that the rest follows the normal distribution, and the models given by equations are suitable for practical technical applications. The developed complex part from the PRT mold is inspected with help of 3D scanner by choosing the best fit function against the model. The results can be easily recognized in this chapter is reported, 18.79 % is the maximum volumetric shrinkage found in cylinder feature and 11.57 % is the least volumetric shrinkage in hollow rectangular prism among all the features.

The last and the fifth chapter of this thesis a systematic methodology is presented using regression analysis and a newly developed MPSO algorithm for determining the optimum process parameters. In this method an efficient greedy selection procedure has been employed for obtaining better position between the newly generated and the current candidate solution based on the fitness value. Furthermore, a real life case study of an electronics component relay is considered for injection molding process. Initially, the effects of the injection process parameters on shrinkage and warpage for various wall thicknesses were examined using Taguchi method. The shrinkage and warpage values were found by Moldflow insight software. The results of confirmation experiments and analysis of variance (ANOVA) assure that the quadratic models of the shrinkage and warpage are well fitted with the simulated values at the optimum value. The shrinkage and warpage have been analyzed and predicted by the obtained mathematical models for the individual effects of all parameters. The adequate value of regression coefficient for shrinkage and warpage indicates that the model is significant and further analysis and predictions can be performed. Moreover, all the linear, square and interaction terms have significant effect on the response output. The influences of all the process parameters on the performances of shrinkage and warpage have been analyzed by the obtained mathematical models. The predicted response of injection molding process also shows an improvement, using a newly developed MPSO algorithm. The MPSO algorithm

overcomes the lack of classical PSO in exploitation behaviour through introduction of an improved search equation based on the best solution of the previous iteration.

Additionally, a greedy selection procedure is added to improve the exploitation ability of the classical PSO. The improvement in shrinkage and warpage is around 30% as compared to the initial values of shrinkage and warpage.

On the basis of work carried out in this thesis, following conclusions have been reported in the five parts of this thesis as,

1. This work proposes a novel framework that replaces conventional molds and provides an AM direct PRT mold as a functional injection molding.

2. This work provided an alternating and optimum path for development of accurate part through PRT mold by minimizing various challenges, issues and by process parameter optimization of plastic injection molding machines. In addition, it investigates the critical parameters and their factors value for accurate feature reconstruction and improved accuracy of developed model.

3. This work proposes a novel inspection planning framework for eliminating conventional CMM/ Vernier caliper inspection planning requiring skill and expertise and provides a best way for inspection of soft materials like parts.

4. The work addresses the significance of 3D scanning process previously ignored in the literature. The effect of geometric attributes on the final accuracy of developed benchmark and complex feature part by PRT mold inserts using non-contact laser scanning is also studied.

5. This work also proposes a complex feature part having benchmark features for GD&T inspection and non-contact scanner characterization. The proposal of complex feature part and methodology for GD&T verification will provide a simple way of performance evaluation for contactless laser-scanning systems.

6. This work proposes an improved variant of classical particle swarm optimization named as modified particle swarm optimization (MPSO). The proposed algorithm overcomes the insufficiency of the classical PSO in terms of weak exploitation behaviour by introducing an improved solution search equation based on the best solution of the previous iteration. Additionally, a greedy selection procedure is added to further improve the exploitation ability of the classical PSO.

7. A simple objective function for geometric error of sample was formulated as an unconstrained optimization problem. Further, the minimum zone objective function was minimized using nature inspired algorithm like GA, PSO and MPSO.

8. The MPSO algorithm is further used in optimizing injection molding parameter and form error. Compared to conventional or existing heuristics optimization methods, the proposed MPSO algorithm not only has the advantage of a simple realization in computers and good flexibility, but it was shown to have improved evaluation accuracy.

### **Scope for Future work**

This research work has given rise to some useful directions which forms the future scope of research. They are as follows:

1. Application of the proposed framework and adopted methodologies in inspection of components produced by other manufacturing processes.

2. Need to explore other injection molding parameters that affect the final output of the reverse engineered models.

3. This study proposes the novel framework for development of part from PRT mold and takes a step towards making the inspection process fully automatic. So, the next step will be to automatize the procedure described in the proposed framework by converting the steps into an algorithm for automatically extracting information from CAD to achieve an integrated GD&T-RE system.

4. Application of other advanced single and hybrid nature inspired optimization techniques for determining optimum injection molding parameters and GD&T error evaluation of developed part.

5. Application of advanced computational tools like Fuzzy sets and neural network will be highly interesting for optimum injection molding parameters and optimizing form error.

2. **Sagar Kumar**, Amit Kumar Singh, Vimal Kumar Pathak. “Modelling and optimization of injection molding process for PBT/PET parts using modified particle swarm algorithm” in Indian Journal of Engineering and Material Sciences (IJEMS), Ref: NISCAIR (IJEMS-9642)/18. (SCI)
3. **Sagar Kumar** and Amit Kumar Singh. “FDM modeled polymer tooling for Plastic Injection Molding” in International Journal of Advances in Materials Science and Engineering (IJAMSE) Vol.7, No.1, January 2018, DOI:10.14810/ijamse.2018.7102.
4. **Sagar Kumar** and Amit Kumar Singh. “Volumetric shrinkage estimation of benchmark parts developed from rapid tooling mold insert” Sadhana, submission id: SADH-D-18-00150 (Under review on 01-Feb-2018). (SCI)

### International/ National Conferences

1. **Sagar Kumar** and Amit Kumar Singh. “Dimensional issues of polymer based rapid tooling mold inserts” *International Colloquium on Materials, Manufacturing and Metrology*. 2014, IIT Chennai, India.
2. **Sagar Kumar** and Amit Kumar Singh. “Dimensional Accuracy of RP pattern and RTV mold Using Taguchi technique” *International conference on AM, 3D printing and 3D scanning (ICAM-3D)*. Feb 2015, Chennai India.
3. **Sagar Kumar** and Amit Kumar Singh. “Integrated product design and development through rapid tooling for sustainable manufacturing” *National Conference on Sustainable manufacturing (NCSM-2015)* MNIT Jaipur, January 2015.

## BRIEF BIO-DATA OF THE AUTHOR

Name: **Sagar Kumar**

Date of birth: February 20, 1988

Address for correspondence: Flat G1 Wing 03 Glory Apartment

Vinayak Enclaves, Near Gyan Vihar University

Ramnagariya, Jagatpura, Jaipur- 302025

### Education:

Qualification	Discipline	University	Year of Passing	School/college
Ph.D.	Machine Design	Autonomous	2019	MNIT, Jaipur
M. Tech	CAD/CAM	Autonomous	2012	VNIT, Nagpur
B.E.	Mechanical	VTU, Belgaum	2010	Sir MVIT, Bangalore
Intermediate	Science	BIEC, Patna	2004	M.M. College, Patna
Matriculation	General	BSEB, Patna	2002	P.H.S, Patna

### Teaching/Research Experience:

University/ Institute	Duration	Designation
ARMJET, Mumbai	Jun 2012- July 2013	Assistant Professor
MNIT, Jaipur, (Rajasthan)	Dec 2013- Feb 2019	Ph.D. Research Scholar
